From Fig. 1 we conclude that : (1) Genetic recombination between *i*1 and *i*2 occurs. Therefore, two different loci, *i*1 and *i*2, are involved. (2) The situations (*A*) in which an *i*1 lysate infects an *i*2 lysogen, and (*B*) in which an *i*2 lysate infects an *i*1 lysogen, give rise to entirely different curves of recombination as a function of time. Therefore, *i*1 and *i*2 are physiologically dissimilar. (3) In (*B*) the yield of recombinants drops steadily when *t* exceeds 10 min., after a small initial rise ; in (*A*) there is a very considerable and unexpected rise in recombination between $t = 0$ and $t = 20$ min. We conclude that if an *i*1 phage infects an induced cell too early, it is unable to wait within the cell for a later increased chance of fruitful recombination, that is, that the intracellular vegetative (recombining) form of *i*1 phage is unstable. For this concept we have independent evidence which will be published in detail elsewhere.

Sodium and Potassium Changes occurring in the Hæmolymph of Insects at the Time of Moulting and their Physiological Consequences

AN insect is in an extremely vulnerable condition during a moult, so that its behaviour must be completely adapted for the time being to the special problems associated with the moulting process. Ordinary reflexes and locomotor activity must be suppressed. It may even be harmful for some of the muscles to contract at this time while the cuticle is soft, for if they do so they will effect permanent distortions in the drying exoskeleton. The means by which the muscular activity is modified or suppressed are not known.

When a nymphal locust approaches the moult it ceases feeding and becomes progressively less and less active. For a few hours before the moult and for a few hours again afterwards, it is almost motionless, except when it is seeking a suitable position in which to moult. Reflex movements of the limbs can still be evoked at this time but the mechanical responses are extremely feeble. The weak muscular contractions may be partly due to the softening of the exoskeleton, and to internal changes in the muscle fibres, but electrical records obtained from the leg muscles of nymphal locusts with intracellular electrodes suggest that a partial neuromuscular block is present. The block is analogous to that produced by raising the potassium concentration in the tissue fluid[1]. The resting potential of the muscle fibres is low and the fast-fibre responses consist largely of junction potentials. About 24 hr. after the moult has been completed the muscle contractions are much greater, though they do not achieve their full power until about the third or fourth day after the moult. At this stage neuromuscular transmission is normal.

An analysis of the hæmolymph of moulting fifth instar nymphs of *Locusta* and *Schistocerca* showed that in each case the potassium concentration is considerably greater than normal. It was decided to study the time-course of the potassium changes leading to the increased level and also any changes in sodium concentration occurring at the same time.

The time of moulting was anticipated by weighing marked hoppers daily and following the progress of

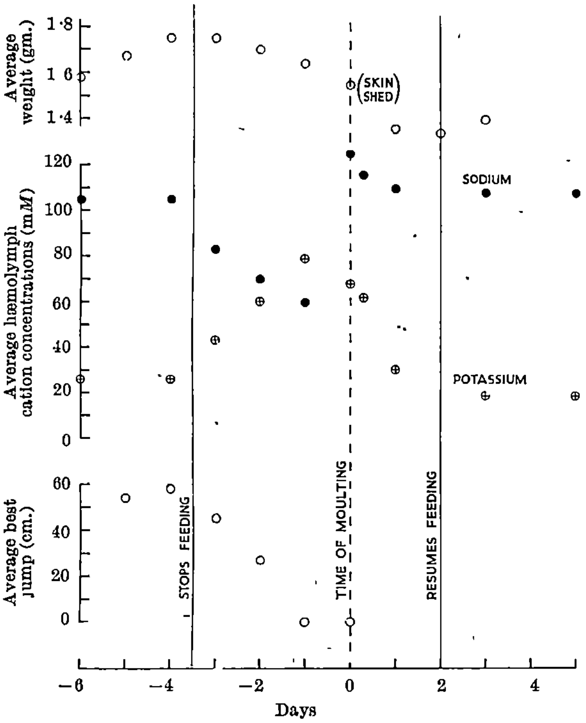

Fig. 1. Physiological changes occurring in fifth-instar nymphs of *Locusta* at the time of moulting. Top, changes in weight; centre, changes in hæmolymph sodium and potassium concentrations; bottom, changes in muscular power indicated by length of jump

each individual graphically. The weight of a hopper rises steadily, increasing by about 0·1 gm./day until eventually the animal ceases feeding. Thereafter the hoppers lose weight at the rate of about 0·6 gm./day, until after about three and a half days following the cessation of feeding the moult occurs. By following the changes in weight it is possible to ascertain approximately the time at which a hopper will moult.

It was found to be possible to follow the progress of a batch containing as many as 40 hoppers. A few individuals were removed from the batch at times estimated to be 4, 3, 2, and 1 days before their moult, during the moult and 6 hr., 1, 3 and 5 days following the moult. 2 c.mm. of hæmolymph was withdrawn from each hopper after making a small puncture behind the pronotum. The sodium and potassium contents were determined with the aid of a flame photometer. Blood was withdrawn from each hopper once only before the moult. Before being returned to the cage each animal was made to jump and the longest jumps were measured.

In Fig. 1 the results of the analyses of the hæmolymph of a group of gregarious-type fifth-instar hoppers of *Locusta migratoria migratorioides* R. and F. are plotted against time in relation to moulting. The average weights, average best jumps, times of cessation and resumption of feeding and the time of moulting are all indicated on the same time-scale. The time of moulting, which was known accurately in many cases or to within not more than 12 hr., was taken as a fixed point. Other points are subject to an error of the order of ±8 hr. in relation to the indicated time of onset of moulting.

The results show that starting at about the time when feeding stops, the potassium concentration in the hæmolymph rises steadily to a peak value of about 80 m.mol./l. while at the same time the sodium concentration falls to about 60 m.mol./l. During this time the sum of sodium plus potassium concentrations remains constant at about 140 m.mol./l. At the moment of moulting both the sodium and the potassium values are extremely variable, but it is evident that there is a fairly abrupt increase in the sodium level, values greater than 200 m.mol./l. having been obtained. There is a corresponding, although smaller, fall in potassium level at about the same time. Thereafter sodium and potassium soon attain the normal adult concentration.

The rise in potassium concentration is adequate to account for the depolarization and partial neuromuscular block which occurs and is probably responsible for much of the inactivity and weakness of the pre-moult hoppers. Potassium ions may therefore play an important part in the achievement of the behaviour changes associated with moulting. Preliminary investigations, now in progress, show that a rise in hæmolymph potassium concentration occurs before moulting in other insect orders.

Change in the Metabolism of Micro-organisms grown on Irradiated Culture Medium

O. Wyss *et al.*[1] report that the growth of drug-resistant pathogen micro-organisms grown on culture media irradiated with ultra-violet rays increased strikingly without the micro-organisms themselves being exposed to the action of irradiation. The experiments demonstrated that mainly in cultures containing protein, under the action of ultra-violet rays the oxidation-reduction potential showed an average decrease of 300 mV., whereas under that of X-rays the decrease was 100–110 mV.; at the same time the value of the redox capacity increased too. In order also to find an energetic explanation for the change of the metabolism of the micro-organisms cultured on irradiated medium the following tests were carried out on aerobic cultures of *Serracia marcesens* strains. The strains examined were inoculated into the medium irradiated with ultra-violet rays of a quartz mercury lamp for 3 hr., and simultaneously the increase of the cell count, the oxidation-reduction potential and prodigiosin production were measured.

It was established that the growth of the cultures only started when the strain had completely exhausted the redox capacity, which had increased on the action of the irradiation of the medium with ultra-violet rays. Afterwards the growth of the cells and the oxidation-reduction potential of the cultures corresponded approximately to that of the controls; the prodigiosin production, however, decreased significantly.

Electrophoretic Evaluation of the Serum Proteins in Malignant Disease

It is well known that many diseases produce a marked alteration in the level of the total serum protein. Furthermore, it has been shown by electrophoretic analysis that certain diseases bring about distinctive changes in the relative concentrations of the different serum proteins. In early active tuberculosis[1] there is a rise in the γ-globulin fraction of the serum protein and a corresponding fall in the albumin-level. As the disease progresses the α^2-globulin concentration also increases and in advanced tuberculosis all the globulin concentrations are raised. In contrast, patients with nephrosis[2] show an increase in the α^2-globulin concentration which is usually associated with a decrease in the γ-globulin fraction.

In malignant disease there is an excessive protein demand by the rapidly growing tumour cells, which can only be met by utilizing the host's dispensable protein and the labile serum proteins. This drain on the body's store of protein is bound to be reflected as a change in the concentration of the different serum proteins. Mider *et al.*[3], using the Tiselius electrophoresis apparatus with a veronal buffer *p*H 8·5, found that the total plasma protein-level in malignant disease was below normal, the albumin-level was reduced but there was a significant rise in the level of the α-globulins ; the β- and γ-globulin fractions also rose but the change in concentration was much less. Peterman and Hogness[4], using a similar method, found that in patients with carcinoma of the stomach the albumin-level was low, the α-globulins were raised, but the β- and γ-globulin-levels were normal. Gross and Snell[5] reported that there was no significant difference between the serum γ-globulin-levels of patients with malignant disease and those of healthy controls.

The present report concerns the results obtained from an electrophoretic evaluation of the serum protein-levels of twenty-four patients from the Dartford Group of Hospitals, Kent, suffering from malignant disease, which had been verified by histological examination. The patients were chosen at random, and their ages varied from thirty-one to seventy years. The majority of the tumours were situated in the genital or intestinal tracts and were at different stages of development, some being localized while others had metastasized widely. Blood samples were taken from each patient on admission and only the blood from those patients having normal temperatures, total and differential leucocyte counts, erythrocyte counts and hæmoglobin-levels were used. Blood samples were also taken from twenty-one healthy females of the same age-group to serve as controls.

The protein-level of each of the sera was estimated by first separating the different fractions by paper electrophoresis at *p*H 8·5 using a veronal buffer. The filter paper strips were then treated with bromphenol blue and the optical density of the protein dye complex was measured by means of a photoelectric cell. In this manner the percentages of the different proteins in relation to the total protein in the serum could be assessed.

The results showed that the sera of the patients with malignant disease had no distinctive electrophoretic pattern. The difference between the α^1-, α^2- and β-globulin-levels of the patients with malignant disease and those of the healthy controls was not statistically significant. The level of the serum albumin, however, was lower in the patients with malignant disease than in the controls. Although these findings are not in complete agreement with those of other workers it must be appreciated that only those patients having normal temperatures and blood pictures were used for the present investigation and the stage of development of the malignant tumour in each case was not taken into account.

Intracellular Site of Developing Herpes Virus

A study of the early hours of multiplication of herpes virus in chick embryo cells[1] showed that some 90 per cent of the virus present in the cells at the beginning of incubation could not be detected 3 and 6 hr. later. The method of cell homogenization employed in this work to extract virus for titration left the cell nuclei intact, and the findings of Gray and Scott[2] suggested that the virus lost in the early hours of incubation might have made its way into the nuclei, and so escaped detection. This possibility was investigated.

Chorio-allantoic membranes of 10-day fertile hens' eggs were infected with herpes virus. After 2, 4, 6, 8 and 10 hr. incubation, membranes were excised, washed and put in diluted anti-herpes serum overnight at 4° C. The membranes were then washed, homogenized and diluted. Fixed and stained smears of diluted homogenate showed intact cell nuclei stripped of cytoplasm. The nuclei were deposited by centrifugation and the virus titre of the supernatant 'cytoplasmic fraction' measured. The nuclei were repeatedly washed, then half were suspended in dilute rabbit serum with 0·85 per cent sodium chloride and half in dilute rabbit serum with 6 per cent sodium chloride. These two suspensions were left overnight at 4° C. and then centrifuged, the supernatant containing 6 per cent sodium chloride being regarded as the 'nuclear fraction' and the other as a control. The virus titres of both were measured. Stained smears of the deposits showed that the 6 per cent sodium chloride solution had removed all basophilic material from the nuclei, leaving none intact except for a very few from erythrocytes ; in the control, intact nuclei were numerous. The results of the virus assays, made by the pock-count method on chorio-allantoic membranes, are shown in Table 1.

It will be seen that at each interval the nuclear fraction contained more virus than the control, but less than one-tenth of that found in the cytoplasm. In three repetitions of this experiment the distribution of virus between the fractions has been the same as in this instance. If all the virus lost from infected cells soon after the onset of incubation[1] had entered nuclei these should contain up to nine times as much as the cytoplasm.

Table 1. DISTRIBUTION OF VIRUS IN CHORIO-ALLANTOIC MEMBRANE CELL FRACTIONS IN THE HOURS IMMEDIATELY AFTER INFECTION

Fraction of chorio-allantoic membrane assayed	Number of lesions caused by 0 05 ml. of assayed material from membranes incubated for 2 hr.	4 hr.	6 hr.	8 hr	10 hr.
Cytoplasmic fraction	60	120	50	80	1,000
Fifth wash of deposited nuclei	0	0	1	1	16
Control extract of nuclei	0*	0*	0*	1*	4*
6 per cent sodium chloride extract of nuclei (nuclear fraction)	3*	3*	1*	4*	90

* Average of eight eggs inoculated with undiluted material.

We may conclude, therefore, that the part of the initial uptake of herpes virus which is no longer demonstrable in the infected cells after 3 or 6 hr. of incubation has not entered the cell nuclei. Other hypotheses accounting for its disappearance are discussed elsewhere[1].

Detection by Phenylalanine Tolerance Tests of Heterozygous Carriers of Phenylketonuria

PAULING introduced the term 'molecular disease' for the hereditary condition of sickle cell anæmia, in which the clinical signs in both the heterozygous carriers with the sickling trait, and the homozygous patients with the anæmia, are explained by the fraction of abnormal hæmoglobin molecules present[1]. Only a part of the total hæmoglobin is the abnormal type in the heterozygote with one abnormal gene, whereas nearly all the hæmoglobin is the abnormal type in the homozygote with two abnormal genes. An extension of this concept of molecular disease leads to the prediction that in hereditary diseases associated with the loss of activity of an enzyme, the asymptomatic heterozygotes should be identifiable by having less than the normal amount of the enzyme primarily involved in the disease[2].

The molecule the dysfunction of which is responsible for the hereditary disease of phenylketonuria is the liver enzyme concerned with the oxidation of phenylalanine[3]. Inactivity of this enzyme results in the high blood-levels of phenylalanine, the excretion of phenylpyruvic acid, and mental deficiency. Genetic studies have established this condition to be completely recessive, and no related mental or biochemical abnormalities have been found in the heterozygous parents or siblings of the patients[4]. The above considerations suggest, however, that the fraction of enzyme arising from the abnormal gene in the heterozygotes should be defective. This prediction is supported by the present findings from phenylalanine tolerance tests that known heterozygotes of phenylketonuria have lower capacities for metabolizing phenylalanine than do normal people.

Plasma-levels of L-phenylalanine were determined one, two and four hours after oral doses of 0·1 gm. of L-phenylalanine per kgm. body-weight, given after an overnight fast, in nineteen heterozygous individuals (parents of proved phenylketonuric patients) and an equal number of normal adult controls. L-Phenylalanine was measured by a modification of the bacterial decarboxylase method of Udenfriend and Cooper[5]. The fasting plasma phenylalanine-levels taken before the test in all individuals were within the range of 0·03 – 0·16 μmol./ml. The phenylalanine-levels in the heterozygotes during the test were on the average about twice those of the controls at each of the hourly intervals. The distinction between the groups was particularly clear at the fourth hour and by comparison of the sum of the three hourly levels used as an index approximating the area under the tolerance curve. The test was repeated on several individuals from each group with highly reproducible results. The means and standard deviations and the range of the values found are given in Table 1.

Table 1. PLASMA L-PHENYLALANINE LEVELS AFTER INGESTION OF L-PHENYLALANINE

Values given are the means ± the standard deviation, and the ranges, in μmol. per ml. of plasma, found in 19 adult controls and 19 parents (heterozygotes) of known phenylketonuric patients

	Hours after dose 1	2	4	Sum of hourly levels
Controls	0·55±0·186 (0 30–0·90)	0·55±0·168 (0 29–1·02)	0 30±0·076 (0 21–0·50)	1·41±0 366 (0 87–2 19)
Heterozygotes	1·14±0·187 (0 84–1 44)	1 03±0 187 (0 72–1·44)	0 76±0·292 (0·45–1·62)	2 93±0·458 (2·10–4 02)

Comparison of the two groups on the basis of age, sex, weight, intelligence, or dose per square metre of body surface failed to reveal discrepancies which could account for the observed differences between the phenylalanine plasma-levels of the groups. The possibility was exceedingly small that such a difference could have occurred by chance ($P < 0{\cdot}0001$). The excretion of phenylalanine during the nine hours following the oral dose was determined in about half the individuals. The amounts excreted were not different in the two groups and were insignificant in relation to the amounts disappearing from the blood during the test period. Phenylpyruvic acid in the urine during the same period was never found in the controls, and only in one heterozygote, who also showed the highest observed plasma-levels of phenylalanine. The most probable interpretation of these results is that the heterozygotes as a group have significantly less than the normal phenylalanine-oxidizing enzyme activity.

The test was also of value in distinguishing the phenotype of single individuals. The results in only a small fraction (about 15 per cent) of the individuals tested fell in the zone of overlap between the two groups. With more or less certainty, the remainder of the individuals could be clearly distinguished as belonging to one or the other group on the basis of the phenylalanine-tolerance test alone. The probability that an individual in one group might have levels at the mean for the other group was less than 1 in 20,000. This ability of the test to identify heterozygous individuals was examined in six normal siblings of proved phenylketonuric patients. Three gave results in the heterozygote range (four were expected on a statistical basis) and three were clearly normal. In addition, a typical heterozygote type of curve was obtained and confirmed in one individual whose direct and collateral relatives over four generations did not include any cases of phenylketonuria or mental deficiency. Normal liver function was assumed for this individual on the basis of a negative history and physical examination and a bromsulphthalein test. Although phenylketonuria occurs rarely (1 in 25,000–40,000 people)[4], the heterozygous carriers are very much more common (half the square root of the frequency, or at least 1 in 100 people). In the absence of liver disease, heterozygosity for phenylketonuria is therefore the probable explanation for the high levels found in unsuspected individuals.

While the results in a single individual must be interpreted with caution, the abnormal values found in a group of known heterozygotes establish the decreased ability to metabolize phenylalanine as the phenotypic expression of a single phenylketonuria gene. This finding provides confirmation for the view that lack of the active phenylalanine-oxidizing enzyme is the primary lesion in phenylketonuria. Finally, the presence of part of the enzyme in an inactive form in the heterozygote with one abnormal gene, and nearly all the enzyme inactive in the homozygote with two abnormal genes, extends the concept of hereditary molecular diseases, based until now on the abnormal hæmoglobins, to those diseases called by Garrod[6] "inborn errors of metabolism".

This investigation was aided by a grant from the Playtex Park Research Institute; Grant *A* 567 from the National Institute for Arthritis and Metabolic Diseases, United States Public Health Service; and United States Atomic Energy Commission contract *AT*-(30-1)-901 with the New England Deaconess Hospital.

Seeds of Pure Beta-ray Emitter (Yttrium-90) for Radiation Hypophysectomy

Pituitary ablation has recently been advocated for certain forms of advanced malignant disease with metastases, notably carcinoma of the breast. Such an ablation could be produced by irradiation, and gamma-ray emitters have been used interstitially by some workers[1,2]. For example, 10–20 mc. of radon in gold seeds has been implanted in the gland via the nostril and sphenoidal sinus[1], and seven out of twenty-five patients were reported to have benefited. In some cases, however, it was reported that defective vision ensued, possibly as a result of over-irradiation of the optic nerves or chiasma[1]. Small grains of unscreened radioactive gold metal have also been used[2] and in a series of fifty patients treated over eighteen months no damage to the optic nerves or chiasma was reported. However, with gamma-emitting materials, the danger is always present; it will be considerably less if a pure beta-ray emitter can be used. Colloidal beta-emitting solutions have been injected into the gland[3,4], while other workers[5] have used pellets of yttrium-90. This note is a preliminary account of the radiation properties of similar seeds now in use in this Hospital. They are cylinders of 3 mm. length and 1 mm. diameter and are inserted with a cannula via the nostril using an X-ray image intensifier as a visual aid.

Yttrium-90 is a pure beta-ray emitter with a maximum energy of 2·2 MeV. corresponding to a maximum range of 1 gm./cm.^{2} and having a radioactive half-life of 61 hr. It can be prepared as sintered rods of oxide which are cut to size. The seeds are irradiated in the atomic pile at the Atomic Energy Research Establishment, Harwell, at a high pile factor for a period of several days, the specific activity produced for a six-day irradiation at a pile factor of 12 being about 220 mc./gm. The average mass of the seeds is about 0·0074 gm., so that seeds of total activity of between 1 and 2 mc. are used; the effective activity available for external irradiation will, of course, be much smaller due to self-absorption in the seed.

Each batch of seeds is tested for uniformity by measuring the ionization current produced when the seed is held in the centre of a large ionization chamber. The radiation dose-rate and depth dose from a seed have been determined photographically. Determinations of beta-ray depth dose with film have been reviewed favourably[6]; it has been shown that they reproduced those made with an extrapolation chamber[7] and that they are independent of energy above about 1·5 MeV. maximum beta-ray energy[7,8]. The seed was held on the top of a stack of about 25 pieces of Kodak *K.S.*5 single-coated film which were compressed together in a jig of 'Perspex' and tissue-equivalent wax ('Mix D')[9] so as to give full back-scatter. From the densities observed on each film a depth–dose curve can be drawn; in order to obtain a measurable density on each film in a stack it was necessary to use several different exposure times varying from 20 to 120 sec. Each set of films was calibrated with exposures to a strontium-90 surface applicator of known beta-ray intensity; these also serve to standardize the photographic processing conditions.

The yttrium seeds have been found to give a dose-rate of 3,500 ± 200 rads/hr./mc. at a distance, in water, of 1 mm. from the centre of the cylindrical surface of the seed. Fig. 1 (curve *a*), which is the mean of eight separate determinations, shows the percentage depth dose in the film stack referred to the dose-rate at 1 mm. while (*b*) shows the corresponding derived curve in water which is regarded as equivalent to tissue. Curve (*b*) has been evaluated by measuring the intensity fall-off from the seed in air: from this, together with curve (*a*), the beta-ray absorption in film was calculated; the absorption was then corrected for the difference in density between film and water. The total dose delivered throughout the decay of the seed is 320,000 rads/mc. at a distance of 1 mm in water.

Attempts have been made to deliver a minimum dose of 100,000 rads to the gland by distributing

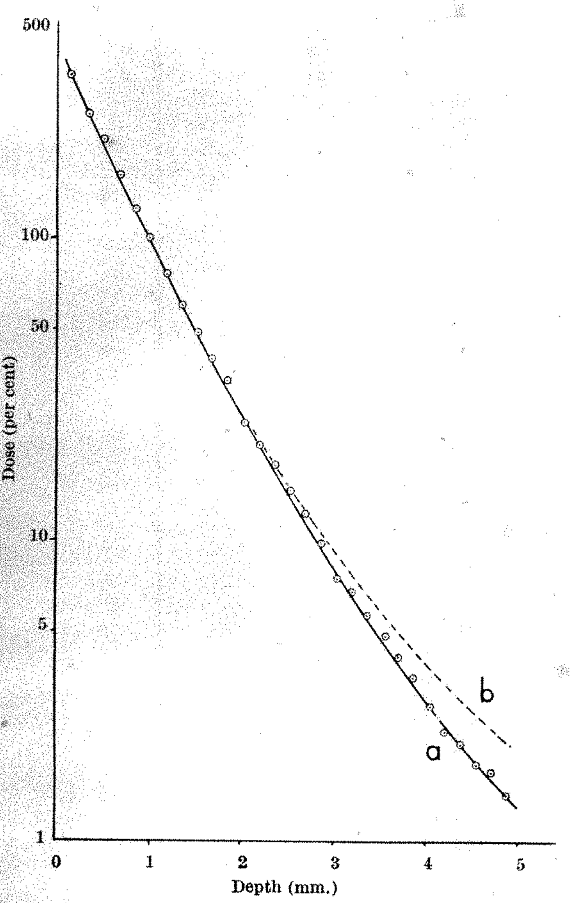

Fig. 1. Curves of dose against depth (100 per cent at 1 mm. depth): (*a*) in film; (*b*) in water

throughout its volume six seeds of average total activity about 9 mc. We are, for the moment, assuming a spherical distribution of dose around the seed.

So far, five patients have been treated, and in due course a more complete account of this technique will be published. We are indebted to Dr. Morrison of the Radiotherapeutic Research Unit and Dr. Russell Fraser of the Department of Medicine, who have carried out the treatments. We are also grateful to the Morgan Crucible Co., Ltd., London, S.W.11, for developing the sintering process.

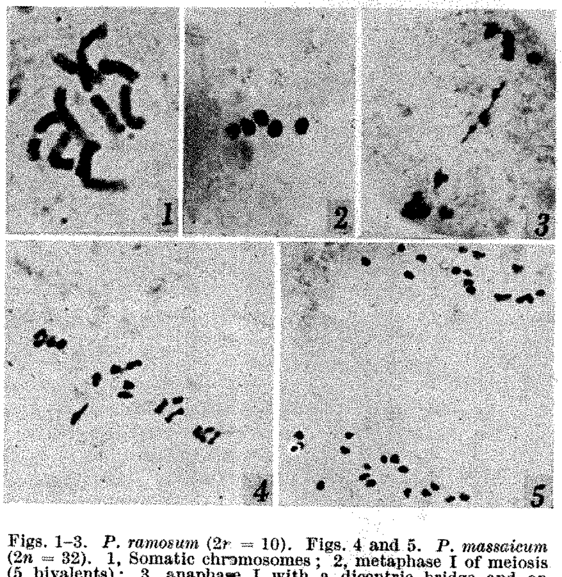
Two New Basic Chromosome Numbers in the Genus *Pennisetum*

Two basic chromosome numbers, 7 and 9, have so far been reported for members of the genus *Pennisetum*, which belongs to the tribe Paniceae of Gramineae[1]. We recently recorded the somatic chromosome numbers 10 and 32 in the species *Pennisetum ramosum* C. Sm. and *P. massaicum* Stapf., which suggests two additional basic numbers, 5 and 8, for this genus. Both *P. ramosum* and *P. massaicum* are natives of tropical Africa and are perennials with profusely branched culms. Both possess all the key characters of the genus *Pennisetum*. Thus, the spikelets are solitary and are surrounded by an involucre of bristles that are free except at the very base. The first glume is shorter than the spikelets; the second glume is almost equal to the sterile lemma in size and the fertile lemma is smooth with a thin margin enclosing the palea.

In the somatic complement of *P. ramosum* one pair of satellited chromosomes was seen and the centromeres in all the chromosomes were either median or sub-median (Fig. 1). At diakinesis and metaphase I of meiosis in microsporocytes, there were five bivalents (Fig. 2). One plant was heterozygous for an inversion leading to the formation of a dicentric bridge and an acentric fragment at anaphase I (Fig. 3). Pollen and seed fertility were high (more than 95 per cent) in all the other plants. Hrishi[2] has considered this species to be synonymous to *P. polystachyon* Shult. ($2n = 54$). From the present data, this view would seem to be untenable.

Besides normal bivalents, quadrivalents, trivalents and univalents occurred at diakinesis and metaphase I of meiosis in *P. massaicum*. The mean frequency per cell of such configurations at metaphase I was $0{\cdot}85_{\mathrm{IV}} + 0{\cdot}125_{\mathrm{III}} + 13{\cdot}625_{\mathrm{II}} + 0{\cdot}975_{\mathrm{I}}$ (average of forty cells). The maximum number of quadrivalents per cell was five. Various irregularities like unequal disjunction of chromosomes, second-division restitution and sporadic abnormalities were observed during the subsequent stages of microsporogenesis. 74 per cent of pollen was stainable.



Figs. 1–3. *P. ramosum* ($2n = 10$). Figs. 4 and 5. *P. massaicum* ($2n = 32$). 1, Somatic chromosomes; 2, metaphase I of meiosis (5 bivalents); 3, anaphase I with a dicentric bridge and an acentric fragment; 4, metaphase I (2 quadrivalents and 12 bivalents); 5, metaphase II with 16 chromosomes at either pole

Seed setting was poor. It seems likely that this plant is a segmental allo-tetraploid.

The existence of a *Pennisetum* species with $2n=10$ suggests that 5 is the original basic number in this genus and that 7, 8 and 9 have all been derived from it since. The results would further support the view that 5 is the primary basic chromosome number for all Gramineae.

We are indebted to Dr. B. P. Pal and Dr. S. M. Sikka for their interest and advice.

A Mutation to Caracul in the House Mouse

IN an inbred line containing no hair-waving factors, but segregating for polydactyly (*py*), leaden (*ln*), and jerker (*je*), mating 19/291 threw one phenotypically wavy animal (19/291.488*b*). She appeared in the first litter and was classified as *py ln je*. As there is no source of this combination of factors in the Department other than line 19, her genotype precludes the possibility of accidental misplacement from some other wavy-bearing stock.

Mating 19/291 continued to breed, producing a total of twenty-three offspring, all of which segregated as expected for the line factors. Their coats and vibrissæ were carefully examined and, with the exception of 488*b*, were found to be completely normal (straight). Thus there is nothing genetically unusual in the mating save the production of the mutation; it seemed most probable that this was dominant and that it occurred in one or other member of the mating and not in a more remote ancestor.

The mutant doe was mated to a buck from another inbred non-wavy stock, and produced seven wavies and eight normals, confirming the dominance of the mutation.

These fifteen progeny and their descendants were used in various crosses (Tables 1 and 2).

Table 1. SEGREGATION OF THE MUTANT GENE

	Wavy	Normal	Total	χ^2
Backcrosses	68	53	121	$\chi^2 (1:1) = 1{\cdot}8595$
Intercrosses	22	10	32	$\chi^2 (3:1) = 0{\cdot}6667$
Outcrosses	57	0	57	

Table 2. LINKAGE TEST WITH NAKED (*N*)

Repulsion backcrosses: wavy/*N* ♀♀ × + + ♂♂

Wavy +	+ +	Wavy Naked	+ Naked	Total	Recombination fraction
40	3	1	46	90	4·4444 ± 0·0217%

The ratios in Table 1 show as a whole a satisfactory agreement with those expected from the segregation of a single dominant factor. However, the intercross ratio is nearer a 2 : 1 than a 3 : 1. This suggests that the mutant gene is lethal when homozygous. To test this possibility several wavies from the intercrosses were mated with normals. Two of them produced no normals out of fifty-seven (see Outcrosses in Table 1). These must have been homozygotes and thus their non-lethality is demonstrated.

The test with Naked (*N*) (Table 2) proves the mutation to be closely linked with it, the recombination fraction being 4·4444 per cent. This is not in good agreement with the value for the linkage of Caracul (*Ca*) and Naked obtained by Mallyon[1] for female gametogenesis, namely, 1·5200 ± 0·0062 per cent. In spite of this discrepancy, which may be due to environmental or to genetic differences between Mallyon's and my own stock, it appears likely that the mutation is, in fact, Caracul. But the possibility that it is a closely linked mimic is being tested.

A New Mechanism for Amide Hydrolysis

PREVIOUS work on acid-catalysed amide hydrolysis has indicated that the reaction is bimolecular: in the rate-determining step the conjugate acid of the amide is attacked by a water molecule[1]. This conclusion is derived from three types of evidence. It has been shown that in concentrated aqueous acid solutions the rate of hydrolysis of a number of simple amides increases with the proportion of water in the solvent[2]; that polar substituents in the acyl part of the amide molecule have very little effect on the rate[3]; and that the rate is substantially diminished by groups, for example, *ortho* substituents in benzamides, which shield the reaction centre from attack by other molecules[3,4].

To determine whether or not there exist conditions under which unimolecular hydrolysis occurs, we have hydrolysed suitably substituted amides in an acid solvent (95–100 per cent sulphuric acid) which possesses good ionizing properties but contains little free water, and which is therefore favourable to unimolecular, but unfavourable to bimolecular, hydrolysis. A selection of the amides studied, together with the kinetic results, is given in Table 1.

Table 1

Result	Amide	Solvent	Temperature	First-order rate constant (10^3 min.$^{-1}$)
1	Acet-3.5-dinitroanilide	100 per cent sulphuric acid	65°	6·0
2	,,	97·2 per cent sulphuric acid	65°	4·5
3	,,	94·9 per cent sulphuric acid	65°	3·3
4	,,	100 per cent sulphuric acid	60°	3·5
5	Propion-3.5-dinitroanilide	,,	60°	9·6
6	Chloracet-3.5-dinitroanilide	,,	90°	<0·1
7	Benz-2.4-dinitroanilide	,,	8°	6
8	4-Nitrobenz-2.4-dinitroanilide	,,	50°	4·4
9	2-Nitrobenz-2.4-dinitroanilide	,,	8°	6

These results have exactly opposite features to those obtained for the amides previously studied first, the rate of hydrolysis decreases as the proportion of water in the solvent is increased (cf. results 1 2 and 3); secondly, polar substituents in the acy group greatly affect the rate (cf. results 4, 5 and 6 7 and 8); and thirdly, *ortho* substituents cause steri acceleration (cf. results 7, 8 and 9). The results are however, completely consistent with the unimolecula mechanism:

$$R'\mathrm{CONH}R + \mathrm{H_2SO_4} \overset{\text{Fast}}{\rightleftharpoons} R'\mathrm{CO}\overset{+}{\mathrm{N}}\mathrm{H_2}R + \mathrm{HSO_4}^-$$

$$R'\mathrm{CO}\!-\!\!\overset{+}{\mathrm{N}}\mathrm{H_2}R \xrightarrow{\text{Slow}} R'\mathrm{CO}^+ + R\mathrm{NH_2}$$

he slow step being followed by rapid conversion of he amine to its conjugate acid, and of the acyl ion o the corresponding carboxylic acidium ion[5].

A fuller account of this work will be published later.

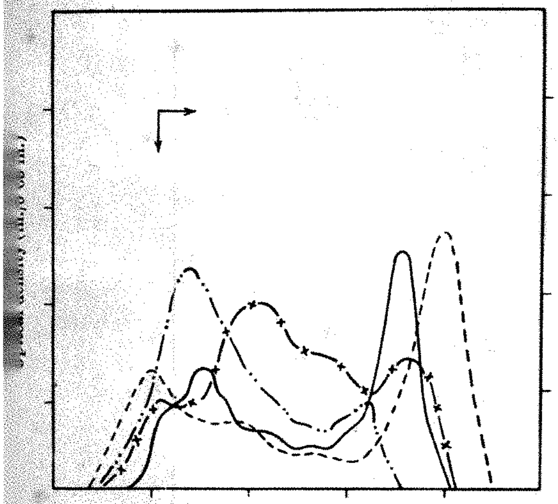
Detection by Paper Electrophoresis of the Protein Denaturation in Heat-inactivated Serum for the Complement Fixation Reaction

In seeking the mechanism to explain an apparent rocomplementary activity to canine complement of anine serum activated at 56° C. for 30 min., it as observed that the same serum was anticomple- entary if inactivated at 62° C. instead of 56° C.

Wiggin[1] suggested that the anticomplementary ction of serum depends on the relationship between e protein ratio in the serum being tested and that in e serum being used as a source of complement. ince in the above case both the serum and comple- ent originated from the same animal, experiments ere designed to find out whether serum inactivation 62° C. affected the protein ratio.

Hæmoglobin-free sera which were obtained from ealthy adult dogs were used throughout the present ork. The sera were clarified by centrifugation at 500 r.p.m. and pooled. Fresh or heated (at 56° C., 2° C. or 65° C.) samples of the serum-pool were plied in 0·01 ml. amounts to Whatman No. 1 ter paper strips for electrophoretic separation of the proteins. The electrophoresis equipment in use was *X*118 'EEL' (Evans Electroselenium, Ltd.). The buffer solution was 30·0 gm. sodium barbitone, 19·5 gm. sodium acetate (hydrated) and 205·0 ml. N/10 hydrochloric acid (these were made up to 3 litres of distilled water). The electrophoresis proceeded in two baths (total 12 strips) for 29 hr. at a current of 0·75 m.amp. per strip. Paper strips were stained with 0·25 per cent bromphenol blue and 95 per cent ethanol saturated with mercuric chloride. Quantitative evaluation of proteins on the paper was by direct photometry of the strip.



ig. 1. Paper electrophoresis of canine serum either fresh (full ne) or heated for 30 min. at different temperatures (broken lines): – – –, 56° C.; —×—×, 62° C.; – · – · · · 65° C. Arrows indicate site of application and direction of run

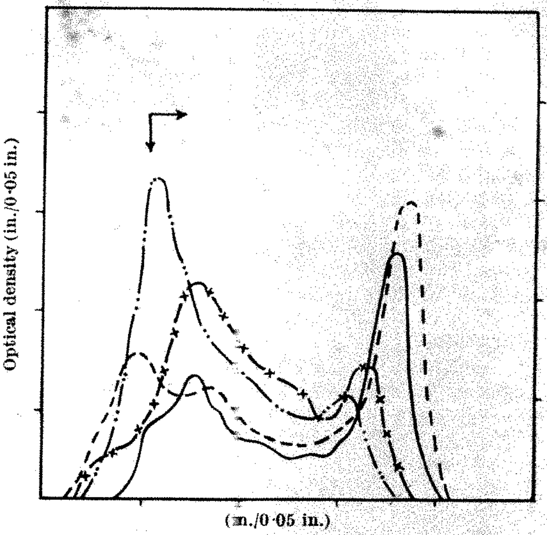


Fig. 2. Paper electrophoresis of canine serum either fresh (full line) or heated for 1 hr. at different temperatures (broken lines). — — —, 56° C.; —×—×, 62° C.; —·—·—·, 65° C. Arrows indicate site of application and direction of run

Fig. 1 shows that heating of canine serum markedly affected electromigration of the protein particles. It is apparent that after heating serum at 56° C. for 30 min. the protein particles migrated faster if compared with unheated serum. Heating of serum at 62° C. or 65° C. for 30 min. reduced considerably the electromigration. Here the protein was strongly adsorbed in the paper and formed patterns which were entirely different from those obtained with unheated serum. The protein denaturation, as shown in Fig. 2, was more marked in samples of serum which were heated at the above temperatures for 1 hr. instead of 30 min.

These experiments suggest that the serum protein can be denatured by temperatures which are commonly used for inactivating serum for the complement-fixation reaction. Detection by paper electrophoresis of protein denaturation at these temperatures has not hitherto been described. Secondly, it seems that, as a function of the serum protein, the procomplementary or anticomplementary activity probably depends on the electric charge on the protein particle in the serum being tested.

A full account of these and related experiments will be published elsewhere.

A Light Source for locating Œstrogens on Chromatograms

As part of an investigation at this Station into the reproductive physiology of sheep, a suitable light source was required for detecting traces of œstrogens on paper chromatograms of blood extracts. Œstrogens have an absorption maximum near 280 mμ, and light near this wave-length gives maximum contrast when used for photographing them on filter paper. The mercury-vapour lamp is commonly used for this purpose, but its emission in this region is weak and a train of filters is required.

On the other hand, the magnesium spark emits most of its photographically active radiation between 2791 and 2803 A., and a spark system assembled from readily available components has proved simple and convenient in operation. The transformer was of a type used commercially for neon lighting, with a secondary rating of 15,000 V., 30 m.amp., the 0·0025 μF. condenser was assembled by soldering forty 0·1 μF., 500 V. radio condensers in series and the 0·01 μH. coil consisted of seven turns of 14-gauge copper wire on a 3-in. diam. 'Tufnol' tube. The electrodes were made by winding two helices of magnesium ribbon about 1 cm. in diameter held approximately 6 mm. apart.

Photographs taken through No. 1 Whatman filter paper in contact with Ilford reflex document paper using 10 sec. exposure at 70 cm. enabled spots down to 1 μgm. œstrone/sq. cm. to be detected. Using a 4-cm. filter of nickel sulphide and cobalt sulphate to reduce undesirable radiation failed to give any apparent increase in sensitivity.

Although the spark system is run in air, the electrodes can be operated continuously for periods up to one minute without igniting.

A New Detector for Vapour Phase Chromatography

Vapour phase chromatography has been used with great success in these laboratories for the analysis of the products of reactions in the gas phase. By using a thermal conductivity detector it has been possible to estimate amounts of product of the order of 10^{-8} mole; but this was the lowest limit which could be reached. In certain cases, however, it became necessary to detect 10^{-12} mole of a substance. The detector described below has been developed to meet this requirement. It is of wide applicability and is easil constructed.

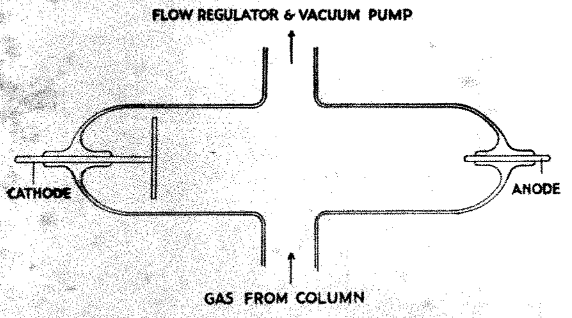

Fig. 1. Glow-discharge detector

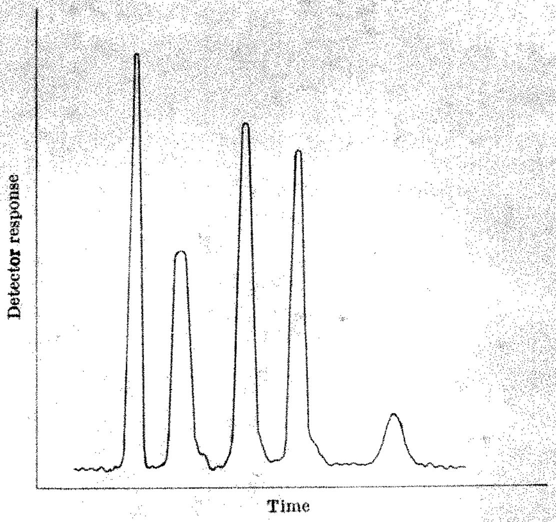

Fig. 2. Detection of components of paraffin mixture

Use is made of the fact that the voltage existin across a normal gaseous discharge is a function of th type of gas used. This voltage changes by severa volts with the introduction of a minute amount c impurity into the gas. The detector consists of a sma platinum disk cathode and a tungsten wire anod (Fig. 1) forming one arm of a Wheatstone bridge whic is supplied with 900 volts from a stabilized d.c. source The bridge is balanced with carrier gas flowin through the detector at a pressure sufficiently low t produce a normal glow discharge between the electrodes. Compounds eluted from the column cause voltage change across the detector which is measure by a recording potentiometer. Fig. 2 shows a recorc ing of the constituents separated from 10^{-10} mole c petroleum ether (40–60°) on a 4-ft. column of 'Celit and amyl phthalate. Details of the technique will t published later.

Definition of Chromatography

The essence of the classical chromatograph method of Tswett[1] is presented by Ratchinsky[2] the form of the following definition: "Any liqu or gaseous mixture of the substances is divided in its components during the process of its movemer through a layer of sorbent, if there are differenc in sorbtion interaction between the components the mixture and the sorbent". I believe the relati movement of the phases to be the important feature in the case of the movement of the dispersed sorbe through a layer of a liquid or gaseous mixture t chromatographic process of Tswett will be inverte In relation to the aggregate state of the disperse sorbent the inverted method of Tswett thus embrac three varieties of chromatography: (1) suspensic chromatography—when the solid dispersed particl of the sorbent settle or rise through the liquid gaseous mixture[3,4]; (2) emulsion chromatography when the dispersed drops of liquid move through t liquid or gaseous mixture[5]; (3) foam chromatography when the dispersed bubbles move through the liquid mixture[6,7].

It follows that all the varieties of chromatography can be divided into two groups: the group when the liquid or gaseous mixture flows through the layer of the sorbent (classical method of Tswett) and the group when the dispersed sorbent settles or rises through a liquid or gaseous mixture (inverted method of Tswett).

Cathodic Protection of Iron

It has been frequently suggested that the cathodic protection of iron in chloride solutions is due to the depression of its potential to or below the open-circuit potential of the local anodes[1,2]. However, in neutral solutions containing dissolved oxygen the open-circuit potential of the local anodes cannot be measured directly without assuming the previous statement to be true. Nor can it be calculated from the Nernst equation, since the ferrous ion activity in equilibrium with hydrated ferric oxide is unknown. Since the formation of hydrated ferric oxide may be represented by an equation such as

$$4\,\mathrm{Fe}^{++} + 8\,\mathrm{OH}' + \mathrm{O}_2 = 4\,\mathrm{FeO.OH} + 2\mathrm{H}_2\mathrm{O}$$

it is implicit that the open-circuit potential of the local anodes should become more electronegative with increasing pH.

Valuable information on the mechanism of cathodic protection may be obtained by impressing constant currents using an inert anode and measuring the change in potential of iron cathodes with time. Specimens of iron measuring $2 \cdot 5 \times 0 \cdot 5 \times 0 \cdot 088$ cm. the composition of which has been given previously[3] were decreased in benzene, immersed in 0·1 N hydrochloric acid for 1 min., rinsed rapidly in water, dried and stored in dry air for 24 hr. Individual specimens were subjected to cathodic polarization in 100 ml. of sodium chloride solution at current densities of 20 and 40 microamp./sq. cm. using an inert platinum anode. Impressed currents completely protected the iron specimens against corrosion.

Fig. 1 shows potential–time curves on the standard hydrogen scale for the iron cathodes at the two current densities in 1 N sodium chloride (pH = 6·2) and at 20 microamp./sq. cm. in 1 N sodium chloride with the pH adjusted to 8·9 (potentials are expressed on the standard hydrogen scale). Fig. 1 also shows the potential–time curve for uncoupled iron in 1 N sodium chloride.

Although the open-circuit potential of the local anodes on the iron is unknown, it must certainly be more electronegative than the corrosion potential of iron in the same solution. At 20 microamp./sq. cm. at initial pH values of 6·2 and 8·9, potential–time curves for cathodically polarized iron are clearly very erratic, even though the potential of the platinum anode remains completely steady. The form of the curves strongly suggests a process of alternate oxide film breakdown and repair. Separate experiments under similar conditions on iron cathodes oxidized to the first-order violet interference colour show no overall disappearance of colour in 24 hr. and demonstrate that any oxide film on the cathode is not cathodically reduced to soluble ferrous ions at an appreciable rate[3]. After several hours at both pH values, the potentials of the iron cathodes become more noble than that of unpolarized iron, and yet they still remain completely passive. Clearly, under these conditions the potentials of the iron cathodes are more noble than any value that may be attributed to open-circuit potential of the local anodes. Furthermore, the curve at pH = 8·9 is displaced to more noble potentials than that at pH = 6·2, even though increasing pH should move the open-circuit potential of the local anodes in the more electronegative direction.

At 40 microamp./sq. cm. and an initial pH value of 6·2 the potential–time curve is first fairly steady. Separate experiments on iron cathodes oxidized to the first-order violet interference colour show that under these experimental conditions the oxide film suffers cathodic reduction to soluble ferrous ions with an accompanying disappearance of colour within 5 min. Probably the higher impressed current results in partial oxygen depletion at the cathode. Since recent work (Oswin, H. G., private communication) has demonstrated that α-ferric oxide films may be

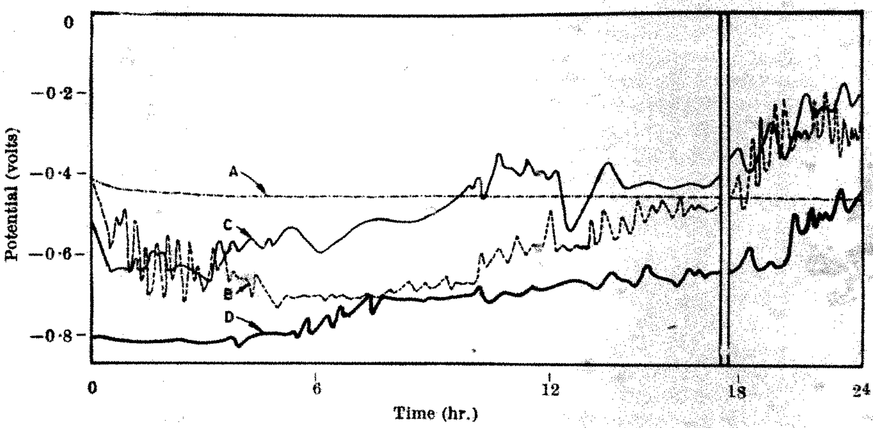

Fig. 1. Potential–time curves for cathodically polarized and unpolarized iron in 1 N sodium chloride at 25° C. A, Corroding iron—no external polarization; B, iron polarized cathodically at 20 microamp./sq. cm., pH = 6·2; C, iron polarized cathodically at 20 microamp./sq. cm. pH = 8·9; D, iron polarized cathodically at 40 microamp./sq. cm., pH = 6·2

cathodically reduced in deaerated solutions at pH values up to 11·0, it is not unreasonable to expect that reduced oxygen content due to the higher impressed current would favour reduction of any initial oxide film on the iron. However, as the pH of the solution around the cathode increases with prolonged cathodic polarization, the efficiency of cathodic reduction of the oxide probably decreases and alternate film repair and breakdown is observed after 4 hr. As film repair gradually achieves ascendancy the potential of the cathodically polarized iron again becomes more noble than that of unpolarized iron.

It is believed that these results indicate that the present theory of cathodic protection is applicable only to a limited number of cases. Clearly, the potential of iron may be depressed enough to make rapid corrosion unlikely from the thermodynamic point of view. Under such conditions the initial oxide film on the iron must be cathodically reduced. If the potential is maintained at the depressed value, perhaps by coupling an active zinc or magnesium anode, the oxide film will not re-form.

However, many cases of cathodic protection must exist where prevention of corrosion can be attributed to an entirely different mechanism. These would include the protection of iron by coupling to high-purity aluminium, by the use of impressed current densities less than 40 microamp./sq. cm., and by coupling to zinc the potential of which had been somewhat ennobled by the formation of corrosion products. In these cases the oxide film is not cathodically reduced. Instead, the function of the cathodic current is probably to reduce the rate at which iron ions leave the metallic lattice. The kinetics of the competing reactions of corrosion and protective oxide film formation are thus disturbed, and the evidence from Fig. 1 indicates that oxide will progressively cover the surface and help to prevent further egress of iron ions from the metallic lattice. During the gradual build-up of a protective oxide film, localized film breakdown, either due to localized reduction of the film or else to undermining by chloride ions, occurs as evidenced by the rapid potential fluctuations. However, these active areas are evidently later repaired by oxygen in solution as the potential continues to move in the noble direction and passivity is maintained.

This kinetic mechanism of cathodic protection is essentially similar to a recent mechanism proposed for anodic inhibition of the corrosion of iron[4] when the inhibitor reduces the rate at which iron leaves the metallic lattice, thereby permitting the formation of a highly protective film of $\gamma\text{-Fe}_2O_3$. It is implicit that higher initial pH values of the electrolyte should also favour the development of the passive state, and it is of interest to note in Fig. 1 that at 20 microamp./sq. cm. the potential fluctuations at $p\text{H} = 8{\cdot}9$ are much slower and the rate of ennoblement of potential higher than at $p\text{H} = 6{\cdot}2$.

A Quantity Analogous to Trouton's Constant

IT is well known that van der Waals, in conformity with the theory of the corresponding states, stated the relation:

$$\ln \frac{p_c}{p} = A\ \frac{T_c - T}{T} \qquad (1)$$

where A is a universal constant.

Such relation is also the result of the application, to the vaporization phenomenon, of Clausius and Clapeyron's equation, integrated at constant heat of vaporization (λ) between the critical temperature (T_c) and another temperature (T) below the critical one:

$$\ln \frac{p_c}{p} = \frac{\lambda}{R}\left(\frac{1}{T} - \frac{1}{T_c}\right) = \frac{\lambda}{RT_c}\left(\frac{T_c - T}{T}\right) \qquad (2)$$

Comparing the two relations (1) and (2) we obtain:

$$A = \frac{\lambda}{RT_c} \qquad (3)$$

Van der Waals gives $A = 6{\cdot}9$. This value applied to equation (1) gives, generally, good results; 6·9 is, however, a median value, and the figure after the decimal point varies with different substances and also at different temperatures.

On the other hand, I have shown[1] that, for normal liquids, the following equation of state is valid (per mole):

$$3\,N_A{}^{1/3}\,V_M{}^{2/3}\gamma = K(T_c - T) \qquad (4)$$

where N_A is Avogadro's number; V_M is molecular volume; γ is superficial tension; and T_c is critical temperature.

The constant K, as well as Eötvös's constant, which is given by the relation $\frac{V_M{}^{2/3}\gamma}{(T_c - T)}$, proves to be a universal constant, independent of temperature.

As Eötvös's constant corresponds, for normal liquids, to a median value of 2·12 ergs, the value of K is found from the following relation:

$$K = 3\,N_A{}^{1/3} \times 2{\cdot}12 \times 2{\cdot}389 \times 10^{-8} = 12{\cdot}86 \text{ cal.} \qquad (5)$$

where $2{\cdot}389 \times 10^{-8}$ is the factor for converting ergs into calories.

I have also shown[2] that:

$$RT \ln \frac{p_c}{p} = 3\,N_A{}^{1/3}\,V_M{}^{2/3}\gamma \qquad (6)$$

Comparing (6) with (4), we obtain:

$$RT \ln \frac{p_c}{p} = K(T_c - T)$$

and, upon dividing by RT:

$$\ln \frac{p_c}{p} = \frac{K}{R}\,\frac{T_c - T}{T} = \frac{12{\cdot}86}{1{\cdot}98}\cdot\frac{T_c - T}{T} = 6{\cdot}5\,\frac{T_c - T}{T} \quad (7$$

The relation (7) shows that the van der Waals's constant, the value of which is 6·5, is a dimensionless quantity, equal to the relation between the normal liquid constant (K) and the ideal-gas constant (R).

The constancy of A that, as previously said, is found by experiment, requires either (a) the mol heat of vaporization (λ) and R (constant for the idea gas) to remain unchanged with temperature (idea case), or (b) such quantities to change in a way tha should keep their relation to one another constant.

In the latter case the behaviour of the vapour wil not be that of the ideal gas, and we shall have t substitute for R the value $\frac{p(v_g - v_l)}{T}$, where p is the equilibrium pressure at temperature T, and v_g and v_l respectively the gas volume and the liquid volume per mole at such temperature.

Therefore relation (3) may be written:

$$A = \frac{T\lambda_s}{p(v_g - v^l)T_c} = \frac{\lambda}{RT_c}$$

where λ_s represents the experimental heat of vaporization.

Taking $(v_g - v_l) = \Delta v$, we obtain:

$$A\ \frac{T_c}{T} = \frac{\lambda_s}{p\,\Delta v} \qquad (8)$$

The above equation shows that the value of the relation $\frac{\lambda_s}{p(v_g - v_l)}$ is the same for all substances when they are in a corresponding state.

In particular, for the normal boiling point (T_e) $p = 1$ atm.) putting $T_c/T_e = 3/2$, we obtain, measuring λ in calories, Δv in litres and p in atm.:

$$A\ .\ \frac{3}{2} = \frac{1}{24{\cdot}12}\ .\ \left(\frac{\lambda_s}{\Delta v}\right)_{Te} = 6{\cdot}5\ .\ \frac{3}{2} \simeq 10 \qquad (9)$$

where 24·12 is the equivalent in calories of the litre atmosphere.

The universal constant, derived in this way, corresponds to half Trouton's constant (λ_s/T_e), nearly.

Equation (9) shows, therefore, that at the normal boiling point, the heat of vaporization is for all normal liquids about ten times as much as the absorbed heat, during the evaporation, required to do the external work (given by $p\,\Delta v$, where $p = 1$ atm.).

Further, since

$$\left(\frac{\lambda_s}{T}\right)_{Te} \simeq 20 \quad\text{and}\quad \frac{1}{24{\cdot}12}\ .\ \left(\frac{\lambda_s}{\Delta v}\right)_{Te} \simeq 10$$

we have also:

$$24{\cdot}12 \left(\frac{\Delta v}{T}\right)_{Te} \simeq \frac{20}{10} \simeq 2 \qquad (10)$$

A Function Multiplier

WE are at present developing, for use in a repetitive ectronic differential analyser of 1 per cent nominal ccuracy, a function multiplier which shows great romise in simplicity and electrical characteristics.

The principle of multiplication based on a geometrical system, amely, a rectangular area which deflected relative to a sys-em of rectangular axes. The xes divide the rectangular area to four rectangles, A, B, C d D, which are equal in area its undeflected position. The eas in the four quadrants are mmed according to the algebraic xpression:

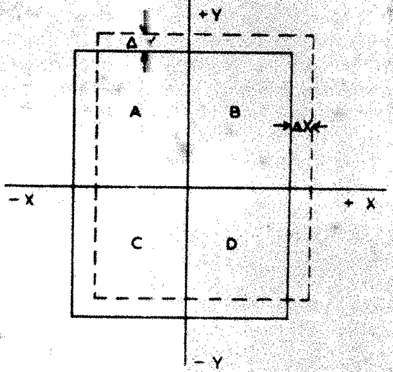

Fig. 1

$$\begin{aligned} R &= A - B - C + D \qquad (1)\\ \text{so that for } A &= B = C = D\\ R &= 0 \end{aligned}$$

If the total rectangular area is displaced a distance Δx in the x direction and Δy in the y direction as shown in Fig. 1, the resultant area as given by the expression (1) above is:

$$R = 4\ \Delta x\ \Delta y$$

Inspection will show that this results in a four-quadrant multiplier yielding the correct algebraic sign of the product and being zero when either Δx or Δy is zero.

A suitable rectangular area was produced on the screen of a cathode-ray oscillograph tube, by defocusing the beam sufficiently to allow the deflecting plates to act as a rectangular aperture shielding the rest of the electron beam. The pattern is deflected by applying deflecting voltages in the normal way, the deflecting plates thus having the dual role of mask and deflecting system.

The area in each quadrant is evaluated by measuring the total light emitted from that quadrant, uniform illumination being produced by saturating the phosphor over the total rectangle.

The light measurement is done by 'piping' the light along four rectangular polished 'Perspex' light-guides on to the photo-cathodes of four 931-*A* photomultipliers. The schematic diagrams of Fig. 2 (left and right) illustrate the method used. This method yields high optical efficiency, and the guide ends nearest the cathode-ray oscillograph face are machined to fit the curvature of the tube. The light at the photomultiplier end is diffused and is proportional to the illuminated area exposed to the input end of the guide. The output currents of the four photomultipliers are summed in a simple feedback adder, the required negative signs for B and C being obtained by suitably connecting the photomultiplier dynodes.

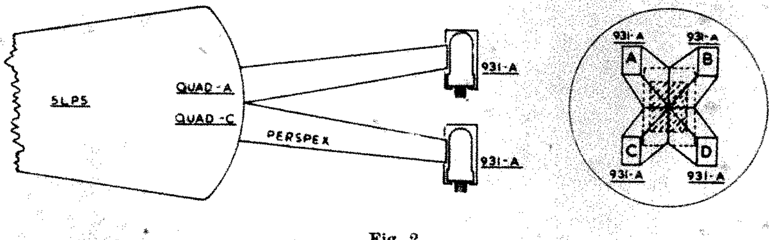

Fig. 2

In an experiment a Du Mont type 5*LP*5 cathode-ray oscillograph tube was used because the deflecting plates gave a good rectangular pattern and the *P*5 phosphor has a high frequency response. Excellent zero adjustment characteristics were experienced and from interpretation of multiplied wave-shapes the linearity and accuracy were deduced to be good. The frequency response is potentially good since all the individual elements used have wide band-widths.

A unit is now being engineered with the view of detailed tests and incorporation in a differential analyser.

I wish to express my appreciation to the President of the Council for Scientific and Industrial Research for permission to publish this communication.

Liquid Crystals of Montmorillonite

If a section of a dry sodium montmorillonite film is placed in a solution of sodium chloride it will swell parallel to the *c*-axis, the swelling increasing as the salt concentration is reduced, until at a sufficiently low concentration (about $N/100$) complete dispersion occurs. This swelling has now been observed under a microscope. Fractions less than 2μ from samples of Wyoming and Dakota bentonites were washed with N sodium chloride and then freed from chloride by dialysis through a cellulose casing, keeping the *p*H of the dialysate about 7·0 by adding dilute sodium hydroxide. An aliquot of the suspended clay was then slowly dried to form an orientated flake about 0·01 cm. thick.

Sections about 0·3 mm. thick were cut with a scalpel from the prepared flakes, placed on a glass slide and a few drops of $N/30$ sodium chloride added. The swelling was observed with the flake on its side, that is, with the *c*-axis of the crystallites perpendicular to the axis of the microscope. The swollen gel showed no structure with ordinary light, but under crossed nicols, on rotating the gel, instead of the extinction being sharp at 90° intervals as each of the nicols in turn became parallel to the *c*-axis, irregular dark bands were observed parallel to the *c*-axis (Fig. 1). The angle between the appearance of the first bands through maximum extinction to the disappearance of the bands was about 20°. The bands appeared independent of the direction in which the section was cut from the flake. The bands were sharpest with very thin gels (birefringence colour, first-order white) and were visible only with the microscope focused on the gel (in particular, with thick gels only on the upper surface of the gels). Between parallel nicols the bands reappeared at an angle of 45° to their original direction. A similar type of band formation has been observed with liquid crystals of tobacco mosaic virus[1]. If the concentration of sodium chloride surrounding the gel was reduced below the flocculating concentration, the bands increased in length and finally disappeared when the specimen became too thin to show birefringence colours. There was no evidence of structure if the flake was viewed parallel to the *c*-axis. The expanded gel from a flake made with the clay fraction less than 0·5μ gave slightly more regular bands there being fewer of the occasional very wide bands present in the gels of less than 2μ particles. Sections from a flake dried only to the 'cheesy' condition gave rise to bands on immersion in sodium chloride but the angle over which the bands appeared was increased to 70°.

A flake was also prepared from a montmorillonite suspension to which a small quantity of a cationi stabilizing agent (*CTAB*) had been added. In the swollen gel the non-expanded crystallites are visible perpendicular to the bands because of their highe birefringence (Fig. 2).

Ross and Hendricks[2] deduced that in dry flakes of sodium montmorillonite the individual platelet or crystallites are arranged approximately paralle to the surface of the flake and randomly orientated perpendicular to this plane. The average width o the bands, about 2μ, is much greater than the diameter of the individual crystallites, 9·6 A. thick many of which are known to be about 1500 A. in diameter. The length of each band is not well defined but is usually greater than 150μ in the expanded gel, corresponding to an unexpanded thickness o clay of 5μ. It is inferred that in the dry flake th crystallites are stacked parallel to the *c*-axis to form crystals of height at least 5μ and diameter 2μ. Th bands are due to the crystals not being exactl parallel to the surface of the flake, so that the opti axes of the crystals are inclined at a few degrees The inclination of the crystals must be random, sinc the bands are observed irrespective of the directio in which the flake is cut. The bands would be expected to be sharpest in the very thin gels, first-orde white corresponding to a thickness of dry clay of 5μ that is, one or two layers of crystals only. From th experiment with the incompletely dried flake, appears that during drying the crystals are forme first and that afterwards the orientation of the crysta is improved. Previous evidence of the existence o montmorillonite crystals is that (00*l*) reflexions ca be obtained from powder photographs.

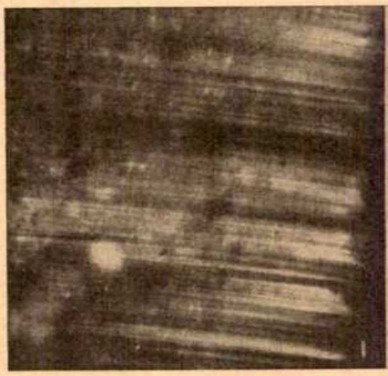

Fig. 1. Sodium Wyoming bentonite in $N/30$ sodium chloride, particles less than 2μ. × 10

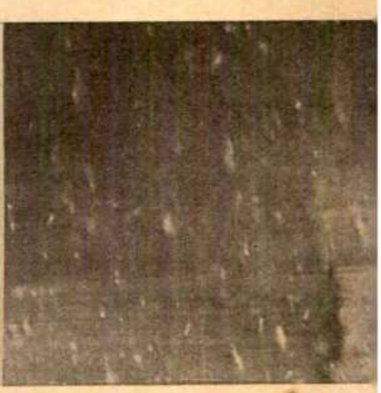

Fig. 2. Sodium Wyoming bentonite + 0·5 per cent *CTAB* in $N/30$ sodium chloride particles less than 2μ. × 100

I wish to thank Dr. H. L. Penman and A. H. Weir for helpful discussions.

Noise Radiation from Tropical Thunderstorms in the Standard Broadcast Band

AN objective method of measuring atmospheric noise interference to broadcasting based on subjective observations and statistical considerations has been reported[1]. Results of systematic measurements by the method in the 3 and 5 Mc./s. bands have been published[2,3]. It has been shown that these results can be satisfactorily explained on the basis of the available data on lightning discharges[4], the distribution of thunderstorm days[5], the growth and decay of thunderstorms[6], and the laws of propagation. For this purpose, the available data on lightning discharges have been utilized to deduce an idealized statistically valid representation of a typical flash as it occurs in a tropical thunderstorm[4]. It is found that

$$P = 45/f^2 \tag{1}$$

where P is the power in watts and f is the frequency in Mc./s.

The calculations are with specific reference to the band-width and time-constant characteristics of the noise meter. It has been assumed that there are three strokes to a flash and that all thunderstorms recorded by weather offices as 'thunderstorm days' radiate noise. It has, however, been clearly stated that the equation must break down for frequencies below 1 Mc./s. This statement was based partly on theoretical considerations and partly on the preliminary investigations[1]. It was therefore felt that measurements of atmospheric noise interference to broadcasting at frequencies below 1 Mc./s. would be valuable not only from the point of view of getting noise data but also for theoretical evaluations. Hence, noise measurements were carried out at 20 and 930 kc./s. at Poona for 18–23 hr. I.S.T., during 1954–56, by C. G. Khot under my direction. Occasionally, observations have also been taken for 2–24 hr. The results have been analysed and the noise data deduced as usual.

Estimates of noise were made as usual by using the power given by equation (1). These estimates were invariably found to be higher than the measured alues. Further, our study of individual thundertorms simultaneously at a number of frequencies ad indicated something abnormal at frequencies elow 1 Mc./s. In order, therefore, to attempt a possible explanation of the results, the lightning discharge data and the original theoretical calculations were re-examined. It appears that the discharges within the cloud or into the air do not radiate any significant power at frequencies below Mc./s., that is, noise radiation at frequencies below Mc./s. appears to arise entirely from thunderstorms n which the discharge strikes the ground. Further, ven in these cases, it is only the stepped leader that s responsible for the radiation of noise. There appears to be no radiation from the dart leaders. Calculations carried out on the basis outlined above resulted in the following expression for the noise power radiated:

$$P = \frac{16 \cdot 2}{f^2} \cdot \frac{1}{\text{[illegible]} + \dfrac{\delta^2}{4\pi^2 f^2 \cdot 10^{12}}} \text{ watts} \tag{2}$$

δ is the constant in the expression for the exponential rise of current in the discharge.

Using equation (2) and the laws of propagation, noise values were estimated, and these appear to agree well with measured values. It appears that equation (2) holds up to 500 kc./s. or even lower. This lower limit has to be evaluated by further experiments. The higher frequency up to which the equation holds lies between 1 and 3 Mc./s. and detailed investigations in this region should prove interesting.

This communication is being published in view of its possible interest to those studying the wave-forms of atmospherics and other problems of thunderstorm electricity during the forthcoming Geophysical Year. The complete theoretical and experimental work will be published in due course elsewhere.

Temperatures in the Earth's Interior

THE melting-point gradient for the Earth's mantle has been determined by Uffen[1] from Lindemann's law; the results yield an upper limit on the actual temperature. Simon[2] and Bullard[3] have made estimates, from Simon's semi-empirical fusion equation, of melting temperatures in the Earth's core, which provide a lower limit to the corresponding temperature in the liquid outer core.

In a recent paper[4], I have derived the Lindemann law from the theory of Debye and Waller for the thermal dependence of the intensity of reflexion of X-rays by a crystal. The development yields[5] a direct derivation of the Simon melting equation, which can be written

$$P_m = A[(T_m/T_{m,o})^B - 1] \tag{1}$$

where T_m and $T_{m,o}$ are the absolute melting temperatures at pressure P_m and zero, respectively, and A is a constant. If the Earth's core is presumed to consist of iron, my results show that

$$B = (6\gamma_{m,r} + 1)/[2(3\gamma_{m,o} - 1)] \tag{2}$$

where $\gamma_{m,o}$ is the Grüneisen constant of the solid at fusion under zero pressure. The applicability of equation (2) follows[5,6] from the fact that iron is sufficiently incompressible for osculating approximations at the origin of the fusion curve to be valid. An

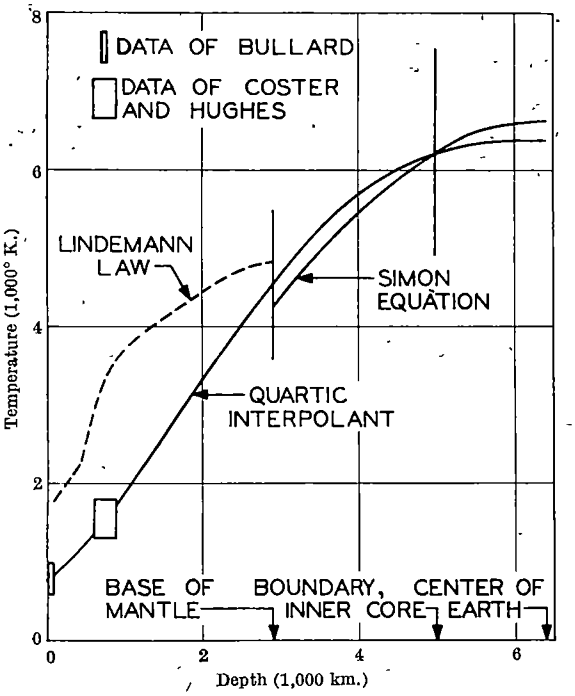

Fig. 1. The fusion temperature in the Earth's core as estimated from the Simon equation, with fusion temperatures (dashed) for the mantle from the Lindemann law (Uffen). The quartic interpolation polynomial yields an estimate of the actual temperature (rectangles and lines indicate possible limits of error)

experimentally verified theoretical relation[4], in terms of fusion parameters, for the Grüneisen constant of a solid at melting yields $\gamma_{m,0} = 0{\cdot}92$, as a mean value for iron; one obtains $B = 1{\cdot}9$ from equation (2). With this value of B and Simon's value[2] of A for iron, equation (1) yields the curve shown in Fig. 1 for the melting temperature in the Earth's core, when the pressure is related to the depth by values from seismic data[3]; Uffen's curve for the melting temperature (corresponding to use of the Debye frequency) in the mantle is shown also (dashed). One notes that the fusion temperature for the inner core is higher than that for the mantle at its base, so that no conflict appears with Jacobs's hypothesis[7] on the origin of a solid inner core. In evaluating B for iron, Simon and Bullard used values for the highly compressible alkali metals as a guide; correspondingly, their fusion temperatures for the core are considerably below those of Fig. 1, and are in conflict[8] with Jacobs's hypothesis.

Bullard[3] has estimated the temperature in the Earth at a depth of 35 km. as 800±200° K. The only experimental evidence on the temperature at depth is the determination by Coster[9] and Hughes (unpublished) of 1,300–1,800° K. as the temperature at which silicates show the low resistivity for a depth of 600–900 km. required by geomagnetic results. Average points from these data are shown in Fig. 1 by rectangles indicating limits of error. At the base of the mantle, computed fusion temperatures yield immediate limits to the actual temperature, which must lie between the fusion temperatures of the liquid core and solid mantle at this point. The temperature at this point will be taken as an average corresponding to the two fusion temperatures in question; possible limits of error are shown by a vertical line in Fig. 1. Further, if the inner core is solid, the fusion temperature at its boundary is the actual temperature (for inner an outer core of the same composition). The fou temperatures in question can be used for constructin a quartic polynomial for the temperature as a functio of depth, when one imposes the constraint that th temperature gradient vanishes at the centre of th Earth (as follows from Gauss's law). The interpolatin polynomial for the temperature T in 10^3 ° K. is

$$T = 0{\cdot}773 + 0{\cdot}750d + 0{\cdot}463d^2 - 0{\cdot}1148d^3 + 0{\cdot}00708$$

in terms of the depth d in 10^3 km. The coefficien are given to the figures shown, merely for prop round-off; the limits of error are given as abo ±25 per cent by the limits indicated in Fig. 1. Th temperatures implied are quite close to those give by Daly[10] for the greater depths in the mantl Inasmuch as the mean temperature gradient pr dicted for the mantle exceeds substantially th adiabatic gradient of 0·17 deg. C./km. estimated b Verhoogen[11] for the (solid) mantle, this temperatu distribution is consistent with solidification of th mantle from the base up. The mean temperatu gradient (0·78 deg. C./km.) for the outer core is clo to the values 0·5–0·7 deg. C./km. for the adiabat gradient which follow from results of Birch[12].

A full account of this work (performed while I w associated with the Rand Corporation, Santa Monic California) will appear elsewhere.

Guarded-Field Ionization Chambers: a New Principle applied to both Free-Air and Thimble Versions

Taylor and Singer[1] placed a system of parall guard wires around the inter-electrode space of 'free-air' ionization chamber, the wires being mai tained at potentials evenly graded between those the collecting electrode and the high-voltage electro respectively. Electrostatic field distortion (large arising from the proximity of the earthed casing) w thereby diminished, enabling the chamber dimensio to be reduced—an important factor in a chamb designed for portability. However, the guard wire taken together, comprise a relatively inefficie screening and field-shaping system[2], and we ha investigated a guard strip system, a cross-secti through the mid-plane of a typical free-air chamb incorporating this system being as shown in Fig. AA', BB', CC', etc., are the sections of rectangul metal (or graphited plastic) frames, which pass alo

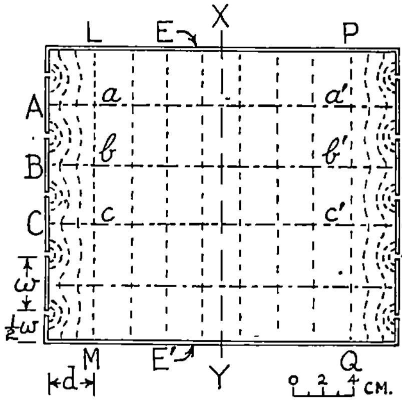

Fig. 1. Mid-plane section of free-air chamber employing guard strips

both sides of the chamber and across the ends, except for small apertures in the ends of the central one (or the central pair, as the case may be), permitting the passage of the X-ray beam. The width w of each of the frames is large compared with the gap g between consecutive frames. Thus w might be, say, 4 cm., and g 4 mm. only. The upper and lower electrode systems E and E' have an edging of width $\frac{1}{2}w$, as shown. Equal potential differences are maintained across all the gaps g. It is easily seen that in these circumstances the horizontal planes (represented by aa', bb', cc', etc.) bisecting each frame, together with the upper and lower electrodes E and E', constitute equi-spaced, equipotential planes. The associated lines of force are somewhat as indicated. It has been found by electrolytic tank studies that these lines (namely, LM and PQ) have become quite straight at a distance d from the guard strips, where d is approximately $\frac{3}{4}w$. The guard system is thus seen to be a very efficient one, enabling particularly compact chambers to be constructed.

An important further step appears to be the extension of this principle to thimble chambers. Thus, imagine Fig. 1 to be rotated about the axis XY. We then obtain a cylindrical chamber, the wall of which can consist of several annular sections separated from one another by very thin washers of insulating material, and possessing a flat circular disk as a collecting electrode. If, in addition, the latter is surrounded by a guard space of appropriate width d, all the lines of force terminating on the collecting electrode will be straight, and the collecting region thereby accurately determined. It has been found that with d equal to one-fifth of the internal diameter of the chamber (the only ratio as yet investigated), the width w of the rings making up the cylindrical wall can be approximately equal to d in value. Fig. 2 shows a section through a practical form of such a chamber, constructed in this case of graphite, and housed in a very thin 'Perspex' shell. 'Terylene' washers, 0·001 in. thick, serve as insulation between the components of the chamber wall. We are also experimenting with chambers of insulating material, the inner surfaces of which are graphited, the cylindrical surface being subdivided according to the above scheme, or screw-cut to provide a steady fall of potential from one end to the other. A very thin and even conducting coating on the cylindrical wall to provide a constant potential gradient may also be possible.

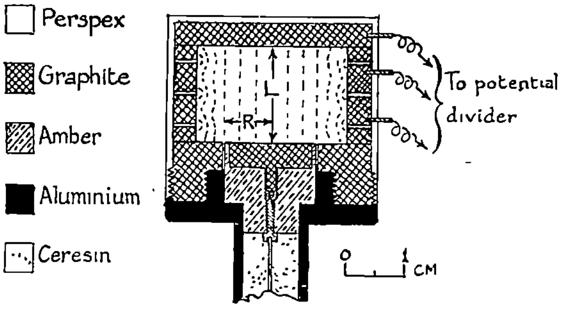

Fig. 2. Section of guarded-field thimble chamber. Note that the top edge of the amber 'cup' holding the collecting electrode is graphite-coated, to minimize the effective gap width. The cup is necessary to avoid charge collection in the gap

Chambers of this type appear to have a number of applications in the study of cavity ionization chambers, and in their use for dosimetric purposes. Among other advantages, the design appears to offer the following:

(i) Geometrical simplicity of the collecting region, enabling its volume to be calculated more easily and more accurately. In particular, the volume depends on knowing two dimensions only: (a) the length L of the cylindrical air space; and (b) the radius R of the collecting region (inclusive of one-half of the width of the gap surrounding the collecting electrode, which can be made very small indeed, namely, approximately 0·1 mm. or less). Furthermore, the elimination of the usual collecting peg, and the fact that the only solid surfaces bounding the collecting volume are plane ones (on which a very high finish can be attained), remove the uncertainties associated with the exact contours obtaining at the junction of plane and curved surfaces which have been machined.

(ii) Completely uniform electrostatic field throughout the collecting volume, thus eliminating regions of abnormally high field-strength, which might prove troublesome in low-pressure studies.

(iii) Complete symmetry of the electrode system, with a resultant simplification of the problems associated with electron emission and exchange.

(iv) Ease of adjustment of chamber volume; annular wall sections can be added or subtracted at will, without disturbing the configuration of the electrostatic field. The collecting volume is thus strictly proportional to its length.

A fuller account of these new chambers and their design data will be published elsewhere in due course.

Opaque Spherules in Dust collected at Isolated Sites

A YEAR-LONG programme involving daily collections of atmospheric dust at several widely separated, isolated sites has been undertaken with the object of identifying particles that may be of extra-terrestrial origin. The particles in question are opaque, shiny spherules with diameters less than 10 microns. They appear to be of a nature entirely different from that of the larger spheres abounding in densely populated areas. Their meteoritic nature is suggested by the fact that the rate of fall and the frequency distribution with size of these particles have been found to be the same at the various stations.

The principal collecting sites were the Smithsonian Astrophysical Observatory's Table Mountain Station above the Mojave Desert of California, a field site of the Geophysical Institute in central Alaska, and the Meteorological Observing Station of the Canadian Meteorological Service at Resolute, North-West Territory, on Cornwallis Island in the Arctic. The collections, begun on July 1, 1955, and completed on June 30, 1956, involved exposing adhesive-covered glass slides to the atmosphere for periods of 24 hr., weather permitting. These slides were scanned under a magnification of 500, making possible identification of particles greater than 3 microns in diameter. Those suspected to be meteoritic were counted and measured after identification by means of tests designed to distinguish them from other types of dust present, involving the use of back lighting, side lighting and polarized light.

The average rate of fall for each station was 1·1 spherules greater than 3 microns in diameter per sq. cm. per day. Assuming that the density of the counted particles is that of iron, this rate corresponds to an annual accretion for the entire Earth of about 10^9 kgm. of these particles.

These results are of interest in relation to the work of Thomsen[1] and of Buddhue[2], who have studied spheres of greater abundance and larger size. No particles of the type they describe were found in the collections from the three principal stations of this programme. Other investigators, notably Crozier[3] and Kizilirmak[4], have studied the magnetic components of dust in the air at their respective institutions.

A promising beginning has been made with an analysis of individual particles by X-ray diffraction techniques. The results of this work will be included in a comprehensive report to be submitted to *Geochimica et Cosmochimica Acta*. A subvention of this project by the Office of Naval Research and the co-operation of the Directors of the collecting stations are gratefully acknowledged.

Dried Breadfruit

In many of the Pacific territories breadfruit (*Artocarpus altilis* Forst.) constitutes a staple part of the diet. Excepting fermentation procedures, no means of preserving this food in the Pacific islands have previously been described. It has recently been reported[1] that the people of the Reef Islands in the British Solomon Islands Protectorate dry breadfruit for use when it is out of season. It is used also as an item of trade with some of the nearby islands.

The method used for drying is to cook the fresh ripe fruit in the ashes of a fire for an hour. The cooked product is left for a day and then it is peeled, the seeds removed, and it is cut into small pieces which are arranged on a net to a depth of four or five inches. This net is suspended over a smokeless fire and the pieces are turned continuously for about six hours.

The dried breadfruit may be kept for twelve months or more if it is stored in coconut baskets on racks above the kitchen fireplace.

A sample of the dried breadfruit was sent to this laboratory. The composition of the product is given in Table 1 together with results obtained for fresh breadfruit from Western Samoa. It is noted that the calcium content of the dried breadfruit is much higher than would be expected from the fresh breadfruit figure. This may be due to contamination of the product by coral dust during preparation.

Table 1

	Dried (per cent)	Fresh (per cent)
Water	8·0	80·0
Ether extract	2·1	0·5
Crude fibre	4·7	1·2
Total nitrogen	0·68	0·12
Ash	4·2	0·8
Starch (acid hydrolysis)	72·0	12·0
Calcium	0·44	0·03
Phosphorus	0·13	0·03

We wish to thank Mr. J. L. O. Tedder, District Commissioner, Eastern District, British Solomon Islands Protectorate, for supplying us with a sample of dried breadfruit for analysis.

"Fluorimetry"

In a recent communication to *Nature*[1] there appears an article entitled "Determination of Intermediary Metabolites by Enzymic Fluorimetry". May I suggest that the term *fluorimetry* is quite inappropriate in the sense in which it is employed in the article, namely, that of the measurement of *fluorescent light*.

As the words 'fluor-spar' and 'hydrofluoric' show, *fluor* is well established as an abbreviation of *fluorine*. Surely, then, fluorimetry, in a chemical context, can scarcely be interpreted otherwise than as meaning *assay of fluorine*, not the *measurement of fluorescence*.

It would seem unfortunate if the usage here called in question were followed by others; it would certainly be most confusing to foreign workers.

In the absence of a suitable *single* word for the measurement of the intensity of fluorescent light, the determinations referred to in the article would seem properly to be described as 'by fluorescence measurement' or 'by fluorescence estimation'—longer though these are. Brevity may be bought too dearly.

BRITISH ASSOCIATION FOR COMMERCIAL AND INDUSTRIAL EDUCATION (at the Royal Festival Hall, London, S E.1), at 10.30 a.m.—Conference on "Automation, Education and Training".

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Main Chemistry Lecture Theatre, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Prof. B. G. Peters. "Parasitology at Imperial College" (Inaugural Lecture)

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. P. Fraser: "High Intensity Combustion in Chemical Engineering".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. C. L. Champion, Mr. R. J. R. Hancock and Mr. W. Woolfson: "The Design and Construction of a Laboratory for Research in Underwater Ballistics".

Wednesday, December 5

IRON AND STEEL INSTITUTE, IRON AND STEEL ENGINEERS GROUP (at 4 Grosvenor Gardens, London, S.W.1), at 10.30 a.m.—Mr. F. J. Potter and Mr. L. Duffy: "Blowers for Use in Iron and Steel Works"; at 2 p.m.—Mr. V. Barnett: "Gas and Air Compressors".

CIBA FOUNDATION (in the Large Hall, Friends House, Euston Road, London, N.W.1), at 5 p.m.—Prof. R. B. Woodward (Harvard): "Recent Advances in the Chemistry of Natural Products".

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. P. W. Cooke: "The Hydraulics of Drilling Mud Flow".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. P. L. M. Rockwell. "Air Navigation".

SOCIETY FOR ANALYTICAL CHEMISTRY (in the Meeting Room of he Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "Trade Effluents".

Thursday, December 6

PHYSICAL SOCIETY, LOW TEMPERATURE GROUP (at the Royal School of Mines, South Kensington, London, S.W.7), at 4 p.m.—Annual General Meeting, followed by Mr. H. J. Goldsmid. "Thermo-electric Cooling".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), t 4.30 p.m.—Sir Wilfrid Le Gros Clark, F.R S.. "Enquiries into the Anatomical Basis of Olfactory Discrimination" (Ferrier Lecture).

INSTITUTION OF NAVAL ARCHITECTS (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 4.45 p.m.—Mr. A. Augustin Normand and Mr. Bartholon: "Some Problems in Design nd Use of Free Piston Gas Generators on board Ships".

CHADWICK TRUST (in the Lecture Theatre, Wright-Fleming Institute, t. Mary's Hospital, Paddington, London, W.2), at 5 p.m.—Dr. J. N. Morris: "Clinical and Community Medicine".* (Malcolm Morris Memorial Lecture.)

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam treet, Adelphi, London, W.C.2), at 5.15 p.m.—Dr. J. E. Richardson: Technical Education in Nigeria".

INSTITUTE OF REFRIGERATION (at the Junior Institution of Engineers, Pepys House, 14 Rochester Row, London, S.W.1), at 5.30 p.m.—Miss B. Shilling: "Cooling Problems in High Speed Military Aircraft".

SIR THOMAS MIDDLETON MEMORIAL TRUST (in the Auditorium, he Wellcome Building, 183 Euston Road, London, N.W.1), at 30 p.m.—Prof. V. B. Wigglesworth, F.R S: "Insects and the Farmer" (Fourth Middleton Memorial Lecture).

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS ROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Meeting on New and Revised Test Methods".

INSTITUTE OF METALS, LONDON LOCAL SECTION (joint meeting with the London Branch of the Institute of British Foundrymen at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. E. F. Emley: "The Founding of Magnesium".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Sphere and Duties of the Industrial Education Officer".

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the BATTERSEA POLYTECHNIC CHEMICAL SOCIETY, at the Battersea Polytechnic, Battersea Park Road, London, S.W.11), at 7 p.m —Dr. C. H. Bamford: "Properties and Configuration of Large Molecules".

BRITISH GLACIOLOGICAL SOCIETY (at Bedford College, Regent's Park, London, N.W.1), at 7.30 p.m.—Annual General Meeting, followed by Mr. G. A. Kellaway: "Frost Heaving and Thermokarst Phenomena in Perennially Frozen Regions".

Thursday, December 6—Friday, December 7

BRITISH INSTITUTE OF RADIOLOGY, incorporated with the RÖNTGEN SOCIETY (at Caxton Hall, Westminster, London, S.W.1)—Annual Congress and Exhibition.

Friday, December 7

BRITISH SOCIETY OF RHEOLOGY (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 10 a.m.—Meeting on "Rheological Control of Industrial Processes".

ROYAL SOCIETY OF MEDICINE, OTOLOGY SECTION (at 1 Wimpole Street, London, W.1), at 10.30 a.m.—Discussion on "Noise and Its Effects". Opening speakers. Dr. J. D. Hood, Prof W. Burns, Mr. D. E. Broadbent and Dr. H. F. Schuknecht (Detroit).

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the Royal Entomological Society, 41 Queen's Gate, London, S.W.7), at 10.50 a.m.—Scientific Papers.

PHYSICAL SOCIETY, ACOUSTICS GROUP (at Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Mr. H. J. Pain: "Shock Waves in Gases".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr A. D. S. Carter and Mr. D. A. Kilpatrick: "The Self Excited Vibration of Axial Flow Compressor Blades".

UNIVERSITY OF LONDON at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. R. V. Moore: "The Development of Nuclear Power".* (Ninth of ten University Extension Lectures on "Technology and Industry". Further lecture on December 14.)

BRITISH PSYCHOLOGICAL SOCIETY, EDUCATION SECTION (at the University of London Institute of Education, Malet Street, London, W.C.1), at 6.45 p.m.—Dr. Alice W. Heim: "Some Preliminary Experiments on a Test of Concept-Formation".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Mr. A. E. T Neale: "Newer Applications of Fine Chemicals in the Rubber Industry".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir George Thomson, F.R.S.: "J. J. Thomson".

Saturday, December 8

BRITISH MYCOLOGICAL SOCIETY (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 12 noon—Annual General Meeting.

BRITISH PSYCHOLOGICAL SOCIETY (in the Psychology Department, Birkbeck College, Malet Street, London, W C 1), at 2.30 p m.—Prof. Frank A. Geldard (University of Virginia). "Tactile Literacy".

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. John Usborne: "Watching North American Birds".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

BIOCHEMIST (with at least three years' experience in the procedures of biochemistry or chemical pathology, and a higher degree in biochemistry or physiological chemistry such as the M.Sc., Ph.D., or equivalent) at St. Kevin's Hospital, Dublin—The Secretary, Local Appointments Commission 45 Upper O'Connell Street, Dublin (December 7).

ENTOMOLOGIST (with a first- or second-class honours degree or equivalent and interested in applied entomological research, and preferably with both field and laboratory experience) IN THE TECHNOLOGICAL IRRADIATION GROUP of the Isotope Division—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 667/34 (December 10).

PRINCIPAL (with high academic qualifications and wide experience, preferably including industrial, research, and teaching experience) OF THE ROYAL TECHNICAL COLLEGE, Salford—The Director of Education, Education Office, Chapel Street, Salford (December 12).

LECTURER IN ELECTRICAL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (December 15).

LECTURER, Grade I (with high academic qualifications, and preferably industrial experience), to take charge of the Sub-Department of Malting and Brewing in the Department of Biochemistry—The Registrar, The University, Birmingham (December 17).

Chair of Therapeutics and Pharmacology—The Secretary, The Queen's University, Belfast (December 20).

Assistant Lecturer in Chemistry at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Lecturer or Assistant Lecturer in Applied Mathematics at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Research Assistant in the Department of Chemistry, for work on the fundamental chemistry of grass conservation—The Secretary, The University, Edinburgh (December 31).

Senior Lecturer/Lecturer in Mathematics; Lecturer in Physics; and a Lecturer in Zoology at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (December 31).

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester (January 1).

Lecturer in Experimental Physics—The Registrar, The University, Liverpool (January 2).

Lecturer in Biochemistry at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 31).

Assistant Biochemist (with a B.Sc. in chemistry or biochemistry, or the A.R.I C.) in the Group Laboratory, Crumpsall Hospital—The Hospital Administrator, Crumpsall Hospital, Manchester 8.

Assistant Chemist (with a degree in chemistry, agricultural chemistry or A.R.I.C.), for analytical work on crops and soils—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/9.

Assistant Lecturer (graduate, with experience in teaching or in industry) in the School of Physics—The Registrar, College of Technology and Commerce, Leicester.

Assistant Lecturer (with a university degree in electrical engineering and practical experience in the electrical industry) in the Department of Electrical Engineering—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Biochemist (with a science degree of a recognized university and special experience in medical biochemistry) with the Ministry of Health, Gold Coast Local Civil Service, to take charge of the Biochemistry Division of the Medical Research Institute—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/13/042.

Demonstrator (preferably with a university degree or professional qualification) in the Department of Aircraft Electrical Engineering, to take charge of the everyday running and maintenance of a teaching and research laboratory devoted to work in the telecommunications, radio navigational, radar and microwave fields—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks, quoting Ref. ER/D.

Laboratory Technician (with considerable experience in virology and preferably also in tissue culture work)—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey.

Laboratory Technician (with some training in bacteriological technique and preferably with Inter. I.M.L.T.)—The Secretary, Royal Veterinary College, Royal College Street, London, N.W.1.

Lecturer (Grade II) in the Department of Chemical Engineering—The Registrar, The University, Birmingham 15 (January 1).

Lecturer (with an honours degree or equivalent, and preferably some industrial or teaching experience) in Mathematics at Coventry Technical College—The Director of Education, New Council Offices, Coventry.

Research Assistant (with an honours degree in biochemistry or physiology, or a B Sc. (Pharmacy), with some research experience) in the Experimental Radiation Therapeutics Department—The Administrative Officer, Christie Hospital and Holt Radium Institute, Manchester 20

Senior Scientific Officers/Scientific Officers (with a first- or second-class honours degree in physics or electrical engineering, together with experience of conducting independent research in suitable aspects of electronics), to carry out original research into problems arising in the application of electronics to nuclear physics, and to develop new electronic techniques and methods of use in nuclear physics research—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 1325/34.

OFFICIAL APPOINTMENTS

UNIVERSITY OF NEW ENGLAND

AUSTRALIA

FACULTY OF RURAL SCIENCE

Applications are invited for the position of Research Fellow or Senior Research Fellow in Dairy Science. The successful applicant will be expected to carry out fundamental research on the problem of depressed butter fat percentage in cattle on certain diets Salary will be fixed according to qualifications within the limits £A.1,100 to £A 1,500 for Research Fellows and £A.1,600 to £A 2,000 for Senior Research Fellows, plus cost of living allowance of, at present, £A.81 per annum (males) and £A.61 per annum (females). The appointment will be for three years in the first instance, and may be extended to five years

Further information and the conditions of appointment may be obtained from the Registrar, University of New England, Armidale, N S W. Australia, with whom applications will close on January 7, 1957

W. M. ROBB.
Registrar

COLLEGE OF AERONAUTICS

Applications are invited for the appointment of Lecturer in the Department of Aircraft Electrical Engineering. Salary dependent on qualifications and experience within a range rising to £1,200 per annum with F S.S.U. and family allowance. A university degree or equivalent in engineering or physics is desirable and candidates should preferably (though not essentially) have experience of one of the following: (a) electrical machine design, (b) aircraft electrical installations, or (c) electrical power systems. Successful candidate will be required to lecture at postgraduate level on aircraft and G.W. power systems and to assist in the equipping and supervision of laboratories Opportunities exist for private research work

Applications (quoting reference EP/L), giving full particulars and the names of three referees, should be forwarded to the Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks, from whom further particulars may be obtained.

NEW SOUTH WALES UNIVERSITY OF TECHNOLOGY

SYDNEY, AUSTRALIA

LECTURER IN APPLIED PHYSICS

Salary: £A.1,252 range £A.1,802 per annum, commencing rate according to qualifications and experience. Applicants should possess a degree with honours or a higher degree in physics. Teaching or research experience will be an advantage. The School of Applied Physics is mainly engaged in teaching physics to undergraduates in chemistry and engineering degree courses A degree course in applied physics is also conducted. Good facilities for research are available, particularly in X-rays, optics, vacuum physics, and magnetic phenomena. Successful applicants will be eligible, subject to passing a medical examination, to contribute to the New South Wales State Superannuation Fund. First-class shipping fares to Sydney of appointee and family will be paid

Five copies of applications (including the names of two referees), should be lodged with the Agent General for New South Wales, 56 Strand, London, W C 2, and one copy air mailed in an envelope "University Appointment," to the Bursar, Box 1, Post Office, Kensington, Sydney, Australia, before December 27, 1956.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer or Assistant Lecturer in Mathematical Statistics. The successful candidate will be expected to assist in advisory and research work in addition to his teaching duties. Salary scales per annum: Lecturer, £650 to £1,350· Assistant Lecturer, £550 to £650; initial salary and status according to qualifications and experience. Membership of F S S U and children's allowance scheme.

Applications should be sent not later than January 1, 1957, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

DRUMMOND FELLOWSHIPS FOR RESEARCH in Nutrition. The Managing Trustees will consider in March, 1957, applications for Drummond Fellowships, normally tenable for two years. One Senior Fellowship: value £900 per annum, superannuation and expenses grant. Not more than two Junior Fellowships value £500 per annum, plus expenses grant —Full particulars from Honorary Secretary, Drummond Trust, University College London, Gower Street. W C 1. Completed application forms must be received by January 31, 1957.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF FOOD PRESERVATION AND TRANSPORT

APPOINTMENT NO. 305/46 OF BACTERIOLOGIST

Applications are invited for appointment to a position of Bacteriologist on the staff of the Division of Food Preservation and Transport's Meat Research Laboratory situated in the grounds of the Brisbane Abattoir, Queensland. The Division is concerned with problems of wastage, quality, and efficiency in Australia's food processing industries The question of storage and transport has particular interest because of Australia's comparative isolation from the major food importing nations and the appointee will be required to supervise, under the direction of the Senior Bacteriologist of the Division, the work of a small group of investigators studying the metabolism of phychropilic micro-organisms and the application of the results to the microbiology of chilled and frozen meat. Applicants should possess a university honours degree with bacteriology or biochemistry as a major subject and postgraduate research experience in bacteriology. Prior experience with meat is not essential Dependent upon qualifications and experience appointment will be made within the salary ranges of Research Officer (£A.1,287 to £A 1,912 per annum) or Senior Research Officer (£A.2,022 to £A 2,297 per annum). First-class sea fares will be paid to Australia for the appointee, his wife, and family The appointment will be conditional on a satisfactory medical examination and the successful applicant will be required to contribute to, and eligible to receive benefits from either the Commonwealth Superannuation Fund or the Commonweath Provident Account.

Applications, referring to Appointment No 305/46, and stating full name, place, date and year of birth, marital state, nationality, present employment, particulars of qualifications and experience, and of war service, if any, accompanied by copies of not more than four testimonials, and the names and addresses of at least two persons willing to act as referees, should reach the undersigned, from whom further particulars may be obtained, not later than December 28, 1956

A SHAVITSKY.
Chief Scientific Liaison Officer
Australian Scientific Liaison Office,
Africa House, Kingsway, London, W C.2.

UNIVERSITY OF MALAYA

SINGAPORE

Applications are invited for Lectureship in Biochemistry. Salary scales: For medically qualified candidates £1,295 by £49 to £1,442 to £1,540 by £56 to £1,988 per annum For non-medically qualified candidates £1,148 by £49 to £1,442 to £1,540 by £56 to £1,820 per annum. Point of entry determined by qualifications and experience Allowances· expatriation in range £280 to £308 per annum, cost of living in range £210 to £560 per annum. All paid in Malayan currency. Free passages for appointee, wife and children under 12 years Part-furnished quarters at reasonable rent. Provident fund scheme.

Detailed applications (six copies), naming three referees, by January 31, 1957, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained.

CENTRAL ELECTRICITY AUTHORITY RESEARCH LABORATORIES, LEATHERHEAD, Surrey, require PHYSICAL, ANALYTICAL and ASSISTANT CHEMISTS in an expanding section working on problems arising from the generation of electricity in conventional and nuclear power stations. The problems include the automatic measurement of very low concentrations of impurities in gases, development of rapid methods of analysis of metals and alloys used in nuclear reactors, corrosion at normal and high temperatures in conventional and nuclear plant and the behaviour of inorganic constituents of coal during combustion.

Salaries: Grade 1, £1,175-£1,525 per annum
Grade 2, £995-£1,345 per annum
Grade 3, £930-£1,140 per annum
Grade 4, £735- £910 per annum
Grade 5, £520- £695 per annum
according to qualifications and experience

Candidates for Grades 1 to 4 should have an honours degree, A.R I C. or equivalent, with experience commensurate with grade. For Grade 5, H N C. in chemistry or equivalent experience desirable, but not essential.

Applications, stating age, qualifications, experience, present position and salary, to D. Moffat, Director of Establishments, Winsley Street, London W.1, by December 19, 1956 Quote ref N/930.

MAKERERE COLLEGE

THE UNIVERSITY COLLEGE OF EAST AFRICA

Applications are invited for Assistant Lect
ship in Chemistry Salary scale £939 by £42
£1,065 per annum, entry point determined
qualifications and experience F S.S U. C
allowance £50 per annum per child (maxim
£150 per annum). Free passages for membe
staff and family (up to four adult passages)
appointment, termination, and leave (three mo
every 21 months) Rent according to qua
provided, £45 to £84 per annum (including b
furniture) .

Detailed applications (six copies), naming t
referees, by December 31, 1956, to Secret
Inter-University Council for Higher Educa
Overseas, 29 Woburn Square, London, W.
from whom further particulars may be obtai

LONDON COUNTY COUNCIL

ROBERT BLAIR FELLOWSHIP IN APPL SCIENCE AND TECHNOLOGY

Applications are invited for the award of
Robert Blair Fellowship tenable for one yea
advanced study or research abroad in app
science and technology The value of the aw
is subject to variation, and, if the country sele
should be Canada or the U S A., may be u
£2,000 (subject to income tax). Candidates
be British subjects and at least 21 years of

Further particulars and forms of applica
may be obtained from the Education Of
(EO/WA 14), The County Hall, S E 1 (stam
addressed foolscap envelope necessary), for re
by February 28, 1957. (2270)

BEIT MEMORIAL FELLOWSHI FOR MEDICAL RESEARCH

Notice is hereby given that an election of Ju
Fellows to begin work on October 1 next
take place in May, 1957. Junior Fellows
have successive annual values of £800, £850
£900, for three years As a rule, superannua
benefits are provided, to which the succes
candidates will be required to contribute 5
cent of the annual stipend and to which the T
will make a contribution of 10 per cent Ca
dates must have taken a degree in a faculty
university approved by the Trustees in
Majesty's Dominions, Protectorates and Mand
Territories, India, Pakistan and the Republic
Ireland, or a medical diploma registrable in
United Kingdom. Elections to Junior Fellows
are rarely made above the age of 35 years.
plications from candidates must be received
later than April 1 Candidates must sub
evidence that they can be given accommoda
in the departments where they propose to w
which must be either in Great Britain or Irel.

Forms of application and all information
be obtained by letter only, addressed to the Se
tary, Beit Memorial Fellowships for Medical
search, the Lister Institute, Chelsea Bridge R
London, S W 1. For overseas candidates fo
of application may be obtained from the Se
tary, South African Medical Council, P O
205, Pretoria, South Africa; The Director, C
monwealth Office of Education, Box 3879,
ney, Australia, the Department of Health,
lington, New Zealand, and the Canadian Med
Association, 244 St. George Street, Toro
Canada

DEPLOYMENT OF SCIENTIFIC MAN-POWER IN BRITAIN

THE central theme with which the Advisory Council on Scientific Policy has been concerned during the past year or more is that of scientific man-power in Britain. The results of two inquiries by the Council's Committee on Scientific Man-power have already been published as separate reports. The ninth annual report of the Council, recently issued*, which covers the fifteen months from April 1955 to June 1956, inclusive, is devoted mainly to other matters with which the Council has been concerned; apart from a brief note in which the Council welcomes the Government's announcement of its plans for the expansion of technical education and also the prospect of substantial new developments in the universities during the next quinquennium. Nevertheless, the problem of scientific man-power may be said to provide indirectly the keynote of even the present report.

It is true that, as the Council remarks in this report, everything possible also needs to be done to ensure, by adequate provision for the secondary schools, that there are enough potential students of the right quality to take full and proper advantage of the increased provision for higher education in the pure and engineering sciences. It is no less true, however, that the nation's demand for scientific man-power, in both the pure and the applied sciences, depends on the efficiency with which that man-power is used. It is right that the recent White Paper on the Factory Inspectorate should stress the importance of making sure that at the present time, neither in Government departments nor in industry, nor, it might be added, in the universities or in teaching, should a highly trained scientist or technologist be employed on duties which do not make reasonably full use of his or her special qualifications and knowledge. It is well that the Service Ministries should be pressed hard in Parliament as to the duties on which they employ science and engineering graduates, and that there should be other evidence that it is at least being recognized in industry and elsewhere that such scarce knowledge and skills are to be used with due forethought and economy.

The wise and economic use of scientific man-power depends also on the provision both of ancillary technical assistance and of the requisite aids and equipment. The ninth annual report of the Advisory Council on Scientific Policy does not refer to the former, though, in view of the lacuna in this respect in both the White Paper on Technical Education and the more recent report on Scientific and Engineering Man-power in Great Britain, it might well have been expected to do so if only to clarify the distinction between technical and technological education, and to emphasize that there is need of a really large expansion in the number of technicians. More technicians are undoubtedly needed to ensure that existing resources in scientific and technological man-power are used efficiently, let alone the increased numbers which the expanded facilities for technological and scientific training should provide. There is still very real danger that the expansion of the technical colleges in Britain may be so conducted as to hinder their primary function of providing the necessary technicians, and that the effect of an increase in the number of technologists and scientists may be more than offset by the absence of a sufficient force of supporting technicians.

This ninth annual report is, however, concerned with various aspects of the provision of the ancillary aids, and its common theme might be said to be the provision of means to make more effective use of scientific and technological man-power in Britain. This may not be directly true of the detailed study of the various systems of training engineers in different countries which, with the help of other interested bodies, the Advisory Council is seeking to arrange; but by providing, as the Council believes it would, useful guidance in the development of technological education, this study could well contribute to an increase in the efficiency of technological education, even if it pointed to no economy in man-power there. Even in the United Kingdom, there is a wide range of technical qualifications and methods of training technologists, and there is abundant evidence of muddled thinking, not least in Government circles, about technological education, which such a study could at least help to remove.

Much more serious, however, is the matter of the National Scientific Reference and Lending Library projects. In its eighth annual report, the Advisory Council emphasized once again the importance which it attached to an adequate national service of scientific reference and lending libraries as an essential tool in disseminating the results of scientific research to industrial and other users; and since then there has been strong support for the Advisory Council's view—particularly at the recent conference of the Library Association—some of it referring to the bearing of these projects on the efficient use of scientific and technological man-power.

The Advisory Council's hope that the Government would give firm decisions in favour of an early start on both projects has again been disappointed. Once more the Council has to report that no progress has been made; provision of £2,500 in the current estimates for the purchase of literature for the future National Scientific Lending Library, to be housed for the present in the Science Museum Library in South Kensington, points to a complete failure on the part of the Government to appreciate the vital bearing of ancillary aids on the economic use of scientific man-power. For lack of the material service recommended by the Advisory Council, it is probable that scientific effort representing many times that £2,500 is wasted every year, and there is no sign as yet that the Government is prepared to take any step to arrest this wastage of one of our most precious assets.

---

* Ninth Annual Report of the Advisory Council on Scientific Policy. London: H.M. Stationery Office, 1956.) 1s. 6d. net.

The Advisory Council has been informed that a decision has been taken to place ultimate responsibility for the National Science Lending Library on the Department of Scientific and Industrial Research, and the Department has been authorized to start planning such a library. The Council accordingly hopes that another year will not pass without some concrete evidence that its recommendations are being put into effect. There is no indication, however, that any action is contemplated about the Reference Library project. Moreover, the full advantage of neither project can be gained if it is planned and executed in isolation or without regard to the building up of an appropriate supporting regional system. No confidence can be entertained in the Government's intentions until it takes up these schemes as part of the Science Centre project, and allocates the sum required to make this essential contribution to the efficient use of our resources in scientific and technical man-power.

The Advisory Council, which should certainly be thinking about its next step, does not leave it at that. It cites the difficulty of handling the ever-increasing output of Russian scientific and technical literature as an example of the inadequacy of the national scientific library service in Britain. No simple recipe for dealing with this problem is offered. The Advisory Council is content to outline the main components of the problem as a basis for discussion, but is careful not to divorce its solution from the long-overdue general modernization of library and information service for all scientific and technical literature. The importance of various factors—the extent to which Russian is read and the encouragement of the teaching of Russian as an important modern language in schools and universities, the securing of Russian scientific literature and making it available, its dissemination and translation—varies, but the problems are not unique and apply in varying degrees to literature in Chinese, Japanese and other languages. Since the Department of Scientific and Industrial Research already runs a limited translating service for Russian scientific periodicals and is to be responsible for planning the proposed National Scientific Lending Library, the Advisory Council has invited the Department to survey existing facilities and to consider what additional arrangements are required. This investigation, in consultation with the Advisory Council's Scientific Library and Technical Information Committee, is already under way.

Of a different order are the proposals to establish a national research centre at which a number of high-energy particle accelerators might be installed to provide research facilities for teams from universities and other institutions concerned with nuclear physics, and to set up in Britain a central mineral-processing laboratory to undertake research into the methods of treating low-grade and complex ores and into chemical and other processes of extractive metallurgy which have been successfully developed. The former proposal, which came to the Council from the Atomic Energy Authority, is under discussion with the university authorities. Various bodies during the past few years have urged the establishment of central facilities for long-range research in the latter field, and the Department of Industrial and Scientific Research is at present discussing with scientific and industrial interests the possibility of establishing such a centre. Although the proposals involve a risk that the centre might monopolize the research facilities available, both schemes offer the possibility of increasing the effectiveness of existing workers in this field by providing them with more adequate equipment and technical assistance.

Of a like nature in its bearing on the effective deployment of scientific man-power is the proposal examined by a working party of the Advisory Council's Biology and Allied Sciences Committee to establish in Britain a centre for tropical agriculture. As territories have become self-governing, British experts in the various agricultural and forestry services have been gradually withdrawn and many have left such territories as Burma and the Sudan, either at their own wish or under pressure from the governments of those territories. If Britain is to help the future development of these newly independent territories, she must be able to provide the training and advice in agricultural matters which they still urgently need; and the working party was convinced that an institution in the United Kingdom is needed both to ensure a future supply of British experts in tropical agriculture, forestry and fisheries, and also as a place which citizens of tropical and sub-tropical countries can use as a base and to which they can turn for advice when studying in Britain.

The need is not for a new college or school for tropical agriculture, the place for which is in the tropics; but for an institute which can help in tackling these problems, and others, such as identifying the most urgent and important problems of research, serving as a channel of communication between agricultural interests in tropical territories and British firms at home and as a meeting place and clearing house for inquiries and advice. The working party was not asked to draw up a plan for such an institute, but the Advisory Council is in broad sympathy with the lines on which the working party suggests the problem should be tackled. In particular, it agrees that the proposed institute, while enjoying support from government sources in Britain as well as from industry and philanthropic institutions, should not be itself a government organization. The working party's report has been submitted to the various Ministers concerned, but it would seem that in view of the potentialities of the proposal for economy in scientific man-power, it could well have been backed by something more tangible than the hope that early consideration will be given to the best means of achieving them.

The remaining two matters discussed in the report —the population problems of tropical countries and esearch in independent Commonwealth territories—also bear on the utilization of scientific man-power. The latter problem directly affects the demand for cientific man-power, and the Advisory Council believes it is desirable that the Agricultural and Medical Research Councils and the Department of Scientific and Industrial Research should co-operate n the provision of scientists for work in the independent Commonwealth territories as well as in the Colonial territories, even if it means adjustments in their present powers to operate overseas. These bodies have already been asked to give further thought to the measures necessary, and the Advisory Council is convinced that it is in the best interests of the territories themselves, and of science and scientists n Britain, for British scientists to continue and ncrease their activities and research in the Commonwealth overseas.

Developments here could increase the demand for cientific man-power in Britain, as well as increase the efficiency with which it is used in some fields. The former matter calls for an increase of expenditure and man-power in a field that will require much work before practical results are obtained. The two main lines of approach to this difficult problem of population growth in tropical countries are social research into problems of family life and social attitudes towards them, and physiological research into the ontrol of fertility and infertility. It is essential to build up a store of knowledge in the latter field, as no artificial means of birth control has any prospect of uccess unless it is desired by the people who are to use it. The need for financial support from the United Kingdom for research into problems of family life in these territories became urgent during the past year, for American authorities which have been responsible for a large-scale investigation in Puerto Rico wish to extend their studies to other territories, ncluding British Colonies. Money has been made available for such a project in Jamaica, but similar tudies are needed elsewhere, and there is no guarantee that any funds will be available after the present Colonial Development and Welfare Act terminates in 1960.

The Advisory Council looks to the Medical Research Council in Britain to proceed as fast as possible with its researches into fertility and infertility and the factors affecting them; but it has hitherto been difficult to persuade sufficient scientists to take up this line of work. Nor does this report suggest any assured prospect of adequate financial support from Government or other sources. Here again is an important field demanding a greater research effort, ut one which could ultimately result in the saving f scientific man-power and in the more effective pplication of scientific and technical knowledge. The Advisory Council on Scientific Policy's ninth nnual report displays admirably the bearing of iverse ancillary matters such as equipment and upporting technicians on the demand for scientific man-power and the efficiency with which it is used; ut presumably its very terms of reference prevent t from calling for action with the vigour and firmness which the situation demands.

SIR JOHN RUSSELL, F.R.S.

The Land Called Me

An Autobiography. By Sir E. John Russell. Pp. vi+286+5 plates. (London: George Allen and Unwin, Ltd., 1956.) 25*s*. net.

I ESTEEM it an honour to be asked in my ninetieth year to review the autobiography of so distinguished and unique a personality as Sir John Russell, acclaimed throughout the English-speaking world—and in many countries outside it—as Britain's outstanding agricultural scientist, and I do so with the greater pride as he was born in a village (Frampton-on-Severn in my own county (Gloucestershire), where his father was a nonconformist minister.

Russell has been unique in his combination of profound scientific knowledge (based upon research and experiment) with an unrivalled capacity for imparting it to others in simple, easily intelligible language, untiring energy, a passion for land development in every part of the world and, above all, deep human sympathy and a yearning for the alleviation of human ills. Well might he say, as Abou Ben Adhem said to the Recording Angel, "Write me as one who loves his fellow men". In view of what became his life's career: it is interesting to note that his youthful zeal as a social reformer while running a mission in the slums of Manchester when a student at Owens Cottage developed in him a craving—albeit without worldly means—to establish an agricultural settlement in the countryside into which its degraded and poverty-stricken slum population could be moved, and with that object he sought, and obtained, a post as a lecturer in chemistry in Wye Agricultural College, Kent.

Russell's social settlement scheme proved impracticable. But this it was which brought him for the first time (at the age of twenty-nine) in touch with agriculture and the land. Thereafter the "Land called" him and eventually placed him in the forefront of its most eminent scientific pioneers. He relates how he never saw a hill without longing to climb to the top of it, and this was true in a moral and intellectual, as well as a physical, sense, the dominating motive being the betterment of humanity and of its chief sources of food. Considering his strenuous professional life, his constant journeys to countries in almost every part of the world and the innumerable lectures which he delivered in them, not to mention his recorded observations of their social, political and economic conditions, are among the surprises of this highly instructive and thrilling narrative, besprinkled with humorous anecdotes and quaint sayings. In almost every country that he visited, honorary degrees and other distinctions were conferred upon him.

Among outstanding landmarks in Russell's amazing career were his appointment in 1907, at the age of thirty-five, as director of Rothamsted Experimental Station, our oldest and greatest agricultural research station, the award of the Albert Gold Medal of the Royal Society of Arts, his presidency of the British Association for the Advancement of Science at its Newcastle meeting in 1949, the celebration of his golden wedding in 1951 in the hall of St. John's College, Oxford, and that of his eightieth birthday in 1952 in the Apothecaries Hall in the City of London, and in 1954 the presentation to him by the Queen of the Gold Medal of the Royal Agricultural Society at the Royal Show at Windsor.

Not the least valuable of his life's assets, as he affectionately testifies, have been a devoted and selfless mother and wife. The eminent autobiographer has proved himself in every sense a great Englishman and a fine exemplar to our rising generation.

BLEDISLOE

EDUCATION OF THE LAYMAN IN ATOMIC ENERGY

Facing the Atomic Future

By Prof. E. W. Titterton. Pp. xi+379+6 plates. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1956.) 21*s.* net.

WE have heard a great deal since the advent of the atomic bomb about the social responsibility of scientists and the need for them to teach the public more about the implications of scientific advances. If the scientist is to succeed in this task it is essential that his pupils should be prepared to co-operate with him and to work seriously. At the same time, in the field of education we hear more and more about the importance of preserving breadth in the training of the scientists and technologists through the provision of courses in the humanities. It is not by any means equally obvious to some of our educators that those trained in the humanities should be furnished with a reasonable grounding in science and technology. Indeed, it is alarming to find in some quarters what appears to be a kind of pride in confessing to an almost complete ignorance of science. This situation makes it an extremely difficult, and indeed almost impossible, task to write in an instructive way for a very large cross-section of the educated public. There is a large fraction of those forming the rather nebulous group known as 'intelligent laymen' who have no real grasp of science. To those content to remain in this category there is nothing to be said in favour of the admirable effort of Prof. E. W. Titterton in this volume.

He has written a book which is in no sense superficial in its treatment of a very vast subject, and his book is one which demands concentration on the part of the readers for whom it is primarily intended. In spite of clarity of style, a thorough grasp of the many major topics with which he chooses to deal and the liberal use of analogy, it is, as might be expected, impossible for the author to avoid or gloss over the hard scientific core of the subject. Indeed, the book would fail in its purpose if the author had tried to do so. He chooses then to meet the difficulty fairly and squarely, and he succeeds very well in all the important aspects of his task. Nevertheless, for the reasons already advanced, it is difficult to say with any confidence how far he will achieve the particular aim which is in his mind. The specialist, reasonably conversant with much of the material, will find the exposition a little laboured, whereas the 'intelligent layman' will need to make a determined effort to understand.

It might be questioned whether the author is wise to include so much detail about the existing situation. It is true, as he himself rightly points out, that the great majority of books are out of date; but it is difficult to ensure any really lasting value to a book if it deals very largely with the detailed features of the field, since these may change very rapidly. It could be argued that Prof. Titterton in this book deals somewhat excessively with the present situation and that he includes the particular to an extent which is rather excessive for a book intended for the further education of the 'intelligent layman'.

With these remarks, I have expressed the only doubts that rise to mind. There are many points on which I am perfectly happy. Thinking of the type of reader who is educated in science or engineering, though not necessarily engaged in pursuits specifically involving such education, I can confidently assert that these readers will be rewarded by a careful reading of this volume. It should give them a thoroughly up-to-date and comprehensive knowledge of the many advances that have been made and an idea of those likely to come in the future. They will find a thoughtful attempt to assess these advances in relation to the functioning of society. The same features should make the volume very valuable to those genuinely seeking an understanding—for example, students in extra-mural classes dealing with modern science. Certainly, with a minimum of help from a teacher, the book could become an exceedingly valuable text.

Prof. Titterton divides his volume into three main parts: atoms for peace; atoms for war; and social and political problems of atomic energy. Each part is dealt with in considerable detail, and the first, not unnaturally, accounts for roughly three-fifths of the whole. The second and third parts are roughly equal in length. The author has collected together much of the openly published material on weapons, and he analyses and discusses it in a careful and factual manner. The same approach is made to the social and political problems—he is admirably unemotional in dealing with the many grave issues that are raised. In this part he guides us skilfully through the maze of efforts that have been made to reach international co-operation in the field.

There is another feature of the book that calls for favourable comment. It is difficult to imagine much improvement on Prof. Titterton's selection of facts and figures. Without giving the impression of a pocket encyclopædia in any way, the book contains a very notable store of useful general information in the form of tables. Thus in Chapter 4, on the need for an atomic power source, are found tables giving water-power, coal and oil in terms of geographical location and under a variety of sub-divisions such as annual production and reserves. The tables reveal many interesting and thought-provoking facts such as the power per head of population in various parts of the world. In this respect the book will form a useful addition to the literature, since it has rapidly become increasingly difficult in the great volume of detailed literature on atomic energy to find the more general facts and figures. Prof. Titterton, as befitting the holder of the chair of nuclear physics in the Australian National University, Canberra, gives in some detail the Australian side of the picture.

To the serious reader this book will provide a really comprehensive survey of the subject so far as it has been made available, and it will provide the basis of a well-balanced view of the advances already made and the probable scope in the near future o the field of atomic energy. It will provide him with the background necessary to a continuing appreciation of a very rapidly expanding subject. The serious work of the author deserves serious application on the part of the 'intelligent layman'. Books such as this from practising scientists are the best answer to the call for more education of the public in the specialized fields. They constitute in turn a challenge to the 'intelligent layman' to fulfil his part of the task. The author's efforts should not be in vain, as the book will provide those with a reasonable grounding in the physical sciences with a straightforward but uniquely comprehensive picture of perhaps the most important field of scientific activity and engineering of the present day. It is refreshing to find a book which shows no tendency to the somewhat hysterical approach to the subject evident in the works of others who aim at catching the attention of the layman. The phase in which there was any justification for such treatment is long past, and a sober factual exposition is now required. The book provides this admirably.

BIOLOGY AND MEDICINE OF ATOMIC WARFARE

Medical Effects of the Atomic Bomb in Japan

Edited by Prof. Ashley W. Oughterson and Prof. Shields Warren. (National Nuclear Energy Series: Manhattan Project Technical Section. Division 8, Vol. 8.) Pp. xvi+477. (London: McGraw-Hill Publishing Company, Ltd., 1956.) 60*s*.

MILITARY science is advancing apace, and not least in the development of atomic weapons. Military medicine must necessarily keep abreast of he times. It is now more than ten years since the first atomic bombs were detonated over Hiroshima and Nagasaki to conclude the Second World War. These nominal atomic bombs were then about a thousand times more powerful than the current igh-explosive bombs. To-day, 'hydrogen' bombs are rated at about one thousand times the power of ominal atomic weapons. This volume, therefore, ite though it may appear to be, is a necessary work f reference for everyone in the medical branches of rmed forces and civil defence.

The contents have been hitherto available only in multitude of specialized reports, such as those of he Joint Commission for the Investigation of the Effects of the Atomic Bomb in Japan and its successor, he Atomic Bomb Casualty Commission. This book ummarizes the early reports and supplies much of he evidence in a convenient form. Prof. Ashley Oughterson, clinical professor of surgery in the Yale University School of Medicine, was editor-in-chief of he report (in six volumes) of the Joint Commission. rof. Shields Warren, professor of pathology in the Harvard Medical School, and lately head of the Division of Biology and Medicine of the Atomic Energy Commission, has personally assessed the athological material.

There are two main features to be stressed. First, Although the atomic bomb is a finite weapon whose ffects can be calculated and partly offset, it has made possible the infliction of stunning casualties at far lower cost in men, money and materials than ever before". The medical problems raised are herefore not so much technical as administrative— amely, how to cope with tens of thousands of casualties, as at Hiroshima, with virtually all local facilities estroyed. The element of surprise found the apanese medical administration wanting; but seventy per cent of the total deaths, in Hiroshima ccurred on the first day. At least another 5 to 10 per cent of those who died were so seriously injured that death was unavoidable. . . . It is apparent that if the mortality from atomic bomb explosions is to be effectively reduced, chief reliance must be placed on preventative measures". The second point is that casualties from the secondary effects of blast and from burns presented few novel pathological features. The influence of ionizing radiation on the response to injury was a strikingly new feature, and radiation injury alone was a common cause of death and severe illness. The clinical and pathological features of this syndrome are carefully analysed.

The book is notable for the very large amount of material presented graphically, tabulated or pictorially. There are so many photographs of clinical and histological material that special plates are a rarity, and most of the production is on the very good paper of the ordinary pages. For most of the clinical photographs this is adequate, but many of the photomicrographs are more than usually obscure.

J. F. LOUTIT

BUILDING: MYTHS AND MAGIC

Architecture, Nature and Magic

By W. R. Lethaby. With a Biographical Note by Alfred Powell. Pp. 155+15 plates. (London: Gerald Duckworth and Co., Ltd., 1956.) 16*s*. net.

IT was more than fifty years ago when Mr. W. R. Lethaby, who died in 1931, published a little book with the title of "Architecture, Mysticism and Myth". It was true, as the author rather humorously admitted, that there was very little about mysticism in the book; but the title had some substance in it, since it was the first-fruits of a study of what the author considered to be the less understood causes which were so closely connected with the art of building.

Mr. Lethaby believed that ideas of building and architecture generally were intimately allied with other ideas relating to the general structure of the world, and also that man's concept of Nature and his belief in magical properties had a profound influence on the development of ancient architecture. To Mr. Lethaby, man was primarily a builder, and in his architecture he formed a kind of framework for his explanation of the universe. Thus in viewing man's building processes a mere æsthetic appreciation was not enough: it was only by understanding the religious and magical ideas of any particular epoch that the architecture of the period could be fully understood. After "Architecture, Mysticism and Myth" was published, Mr. Lethaby set to work to re-write his thesis in a more comprehensive form. He found, however, that the mass of material on the early history of man, his myths, his magic and his cults, was so voluminous that he finally gave up the attempt; and it was not until 1928 that he re-wrote, with additions, much of his former material and published it in a series of articles in *The Builder* under the title "Architecture, Nature and Magic". These are the articles which are now reprinted in the present more convenient form and they illustrate not only the wide range of Mr. Lethaby's reading but also the power of his imagination and the depth of his understanding.

In the course of his discussion, the author deals with man's idea of the fabric of the world, with special reference to the world tree and the temple of heaven. He then proceeds to examine these ideas as seen in the architecture of both East and West. Following from these more general considerations, he goes on to consider the more detailed aspects of building, linking up both ornament and style with magical beliefs and the deeper mental processes deriving from the unconscious mind of the master builders. It is here that Mr. Lethaby is at pains to show that modern architecture, when it attempts to copy the past, has lost its soul. To him these sham styles are, as he so graphically puts it, the mere "grimaces of grown-ups". The age of magic has passed: what remains is, to the author of this illuminating book, the mystery of reality, and although mysticism and an outmoded view of the universe have passed away, both mystery and beauty are still left in service and science. If the modern builder is able to achieve a high functional beauty, then he will be able to show in his own architectural creations the same kind of inspired and creative work that Mr. Lethaby has shown to exist in the great buildings and decorative architecture of the ancient world.

E. J. DINGWALL

BOTANY OF BRITISH HILLS

Mountain Flowers

By John Raven and Dr. Max Walters. (The New Naturalist: a Survey of British Natural History.) Pp. xv+240+40 plates. (London: William Collins, Sons and Co., Ltd., 1956.) 25*s*. net.

THE New Naturalist series has proved a potent force in stimulating popular interest in British field natural history during the post-war years, and this latest addition is well in the best tradition of its predecessors—at once informative, authoritative and eminently readable. Already in the series there has appeared a classic concerned with the vegetation of the higher parts of the British Isles in Prof. W. H. Pearsall's "Mountains and Moorlands"; the present volume, as its authors affirm, is scarcely comparable with that of Pearsall as a scientific study, but it is nevertheless in many respects complementary, concerned as it is with the floristic rather than the ecological aspects of the mountain flora.

The book is written in two principal sections: a general one in which the history of the botanical exploration of the British mountains is reviewed and some account given of the nature and history of their flora, and a regional one in which characteristic species of the more important mountain systems of the British Isles are described and discussed. In the appendixes, the authors provide lists of the mountain flora with distribution maps for several species, and keys for the identification of three critical genera with several representatives on the British hills, *Hieracium*, *Alchemilla* and *Salix*.

The chapters concerned with the environment, nature and origins of the British mountain flora in the general section are the work of Dr. Max Walters. He presents the ecological features of montane habitats starkly and in rather general terms; for an appreciation of the subtlety of the interaction of organism and environment in the communities of the hills, the reader would do well to follow his advice and consult other books of the New Naturalist series, notably those of Gordon Manley and of Pearsall. Dealing with the general biology, distributions and origins of mountain plants he is much more at home. Chapte 4 should be particularly informative to naturalist without access to professional journals, containing as it does, an excellent general account of the tren of contemporary thinking about the history of th mountain species of Britain. Included therein is a survey of the evidence obtained from the investigation o Quaternary peat deposits—evidence which has s convincingly confirmed the view of Edward Forbe of more than a century ago, that the arctic and alpin elements of the British flora, now mostly restrict to the mountain summits, are essentially the residu of a tundra type of vegetation once widespread, eve in the lowlands, during the later stages of the glaciation.

Mr. John Raven contributes the historical intr duction, and a number of pleasantly written chapte in the regional section. He is evidently a great love of rare plants, and one who gains much pleasu from the hunt-the-slipper element so conspicuous i mountain botany. He has a lively sense of t principle of relative rarity—that what matters i extracting the maximum entertainment from pla hunting is not so much how common a plant is i area *A*, but how difficult it is to find at all in area Perhaps, however, he does not carry the princip far enough, for his disparaging comments on t general poverty of the Irish mountain flora awake a defensive reaction in at least one of his readers.

Both authors are repeatedly at pains to stress t need for preserving what remain of our mounta plants, and are commendably reticent about localiti for rarities. Nevertheless, one is uncomfortab aware of the grim possibility that a book like thi by its very success in popularizing the British mou tain flora, may increase the threat to its continue existence if it results in even more profligate collec ing. It must be agreed, of course, that a good de of the damage has been done and is being done agents other than collectors; even the weights dried montane herbage in herbaria must be insig ficant compared with the tons converted over t years into mutton. But in the present situati where the 'best' mountain plants often survi happily enough in minor oases, inaccessible to shee and fire although surrounded by burnt and graz deserts, it is the collector who is their most seve enemy. Furthermore, it is not the indiscriminati tyro who forms the greatest menace to the ma mountain species which are distinguished only their rarity, but rather the type of expert who, his vanity, imagines that the needs of his particul herbarium or his special research privilege him ignore the moderation in collecting which he wou so severely enjoin upon others.

As one now expects from the New Naturali volumes, the photographic plates, colour and mon chrome, are mostly of a high standard. Some perha lack the sparkle that a touch of sunshine would ha given, but who would deny that this is appropria enough in portraits of inhabitants of the British hil Most of the illustrations are in fact of native in viduals. Of the exceptions, it is unfortunat understandable enough why it was necessary to vi the Austrian Alps for a photograph of *Pinguic alpina*, but it seems a little superfluous to ha journeyed so far as North Greenland for a picture so accessible a British mountain plant as *Sil acaulis*. In the interests of newcomers to mount botany, some indication of scale might well have be given for the plates.

J. HESLOP-HARRISON

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS* BY SIR CYRIL HINSHELWOOD, F.R.S.

ANOTHER year of intensive preparation reached its climax on November 13 when H.M. the Queen visited the *Magga Dan*, which was to convey the Royal Society expedition to the Antarctic, and when the members of the expedition were presented to her. The ship sailed two days later bearing the good wishes of all, on this combination of physical and scientific adventure which will make an important contribution to the International Geophysical Year. A great debt is owing to all who took part in the arrangements and especially to Sir David Brunt and to Dr. D. C. Martin, who have borne so much of the burden and heat of the day.

When he has completed a year of office, the President cannot but be very conscious of all that he himself owes to the other officers and to the staff at Burlington House. As the activities of the Society increase this becomes more and more one of the major things which need to be emphasized in this address. I must speak specially of the retiring Treasurer, Sir Thomas Merton, who is handing on his great responsibilities after seventeen years of unique service in that office. Sir Thomas took control of the Society's finances at a moment when they were beset by difficulties of all kinds. By a whole series of wise reorganizations, by a brilliant policy of reinvestment and by unremitting vigilance, he not only weathered the storm but has left the financial position of the Society stronger than it has ever been. Sir Thomas not only carries with him our grateful appreciation for what he has done, but also the assurance of an honoured place in the history of the Royal Society.

AWARD OF MEDALS, 1956

Copley Medal : Prof. P. M. S. Blackett, F.R.S.

Prof. Blackett has made important contributions to three main fields of physical discovery : the interaction with matter of fast particles from radioactive sources, the nature of the particles in the cosmic rays, and the magnetism of the Earth. In each of these he has combined outstanding insight and skill with novel developments in instrumentation.

During 1921–31 he was chiefly occupied with the development and operation of automatic Wilson cloud chambers and their application to the precise measurement of the parameters involved in collisions between α-particles and atomic nuclei. He showed that very infrequent inelastic collisions with nitrogen produced the then unknown isotope ^{17}O by the capture of the α-particle and the ejection of a proton.

In this period also he verified, with Champion, the Mott theory of the wave-mechanical diffraction scattering of slow α-particles.

From 1931 onwards he applied and extended the cloud-chamber technique to the study of the collisions involved in the cosmic rays, establishing (with Occhialini) the existence of nearly equal numbers of positive and negative electrons. This confirmed Anderson's discovery of the positive electron a few months before and extended it by giving strong evidence for actual pair production. The 0·5 MeV. scattered γ-rays were recognized by him to arise from the annihilation of positive and negative electron pairs.

Blackett proceeded to study in more detail the nature and the energy spectrum of cosmic-ray particles. Much valuable work on cosmic-ray showers was carried out under his direction, and he himself explained the negative temperature coefficient of the cosmic rays in terms of the decay of the μ-meson.

These detailed studies led to a discovery which opened up a new field when Rochester and Butler in Blackett's Manchester laboratory in 1946 found the first neutral V-particles and in 1947 the first charged V-particles. The identification by the Manchester team of V^0 decay into a proton and a pion and of the probable division of a V^1 particle into two pions, together with the best determination to date of the life-times of V^0 and V^1 neutral particles, are outstanding further discoveries. These were made possible by Blackett's energetic action in moving the equipment to the observatory of the Pic du Midi.

From 1947 onwards he interested himself in the possibility, originally discussed by Schuster, of a 'fundamental' connexion between the angular momentum of a large rotating body, such as the Earth, and its magnetic field. Although experiments conducted and directed by him gave no support to this idea, the sensitive magnetometer designed by Blackett for this work has been used by him and by Runcorn at Cambridge with success in remarkable studies of palæomagnetism and the light it can throw on polar wandering and continental drift.

Throughout his career Blackett has shown great ability and drive in organizing team effort in difficult fields of research. The building up of the Jodrell Bank radioastronomical station by Lovell owes much to him. He was awarded a Royal Medal in 1940 and the Nobel Prize for Physics in 1948.

Rumford Medal : Dr. F. P. Bowden, C.B.E., F.R.S.

Dr. Bowden is recognized as a leading research worker on the properties of solid surfaces. His early work was on the mechanism of the electrodeposition of ions at metal surfaces. He then turned his attention to the nature of the contact between solid surfaces and the mechanism of friction. He showed that however carefully surfaces are prepared they are generally covered with asperities large compared with atomic dimensions. When such surfaces are placed together, they touch at the tips of these asperities, which are crushed down until they are large enough to support the applied load. The area of real contact is thus independent of the size of the bodies and is proportional to the applied load ; it is usually only a minute fraction of the geometric size of the bodies. At the regions of real contact strong adhesion occurs. The resulting friction arises from the shearing of the welded junctions formed at these points and to a lesser extent from the ploughing of one metal through the other.

---

* Delivered at the Royal Society on November 30.

Bowden has shown that because the area of true contact is so small, the work done in overcoming friction can raise the temperature of the local contact points to extremely high values. Ingenious methods for measuring this temperature were developed, and it was shown that in many cases surface melting may be produced which plays a fundamental part in processes such as polishing and the surface flow of solids. With modern physical methods he has studied the effect of surface films and in particular of boundary lubricants on the interaction between solid surfaces. This work forms the background to the modern theory of friction and boundary lubrication. The practical implications of the work are widely appreciated, and it has led to the development of new low-friction surfaces, improved bearing materials and to the development of special lubricants.

Another phase of Bowden's work is the study of fast reactions in solids and the initiation and growth of explosion in crystals. This has led to a clearer understanding of the cause of accidental explosions and improved methods of manufacturing and handling explosive substances.

Royal Medal (A) : Dr. Dorothy M. C. Hodgkin, F.R.S.

Dr. Dorothy Hodgkin has made many outstanding contributions to our knowledge of the structure of complex organic molecules by the method of X-ray crystal analysis. Her best-known work is perhaps that on the structure of penicillin, and more recently her complete elucidation of the structure of vitamin B_{12}. In this work she has shown that it is possible to apply the methods of X-ray analysis to elucidate structures of molecules which are too complex to yield to the ordinary methods of chemistry.

With Bernal she obtained the first X-ray pattern from a protein single crystal (pepsin) in 1934, and from insulin in 1935. Later, with Schmidt, she made the first X-ray study of a virus single crystal (tobacco necrosis virus). With Bernal and Fankuchen she has completed a most comprehensive study of the crystallography of more than eighty sterol derivatives, belonging mainly to the cholesterol and ergosterol series.

It is perhaps in the field of complete structure determinations that her most important work has been done. She was among the first to realize the importance of the heavy-atom phase-determining methods, and these she used to effect the first complete determination of the geometry of a sterol derivative in her analysis of cholesteryl iodide. This was followed later by a similar analysis of a calciferol derivative and of a lumisterol derivative.

The same powerful phase-determining methods of analysis, and in particular her gift of being able to interpret correctly the complex and partially resolved electron-density patterns obtained, have been mainly responsible for her success in finally elucidating the structure of penicillin and of vitamin B_{12}. This last work is the most beautiful and complex analysis which has yet been achieved in this field.

Royal Medal (B) : Dr. O. T. Jones, F.R.S.

Dr. Jones is widely recognized as the most versatile of living British geologists, being equally at home when dealing with stratigraphical, structural, palæontological or petrological problems.

It was he who first worked out in detail the succession of graptolitic sediments in central Wales, thereby bringing order into a vast area which had formerly been quite wrongly interpreted. More recently, with Pugh, he has, by detailed large-scale mapping, in the Builth area, revealed an example of an ancient Ordovician shore-line, with cliffs and beach deposits, thereby proving that large-scale elevation, erosion and deposition of many hundreds of feet of sediments can fall into the time represented by a single fossil zone, which elsewhere is indicated by only a few feet of sediments.

His work has thrown an entirely new light on the origin of certain complex structures in the sediments of the Lower Palæozoic rocks of north Wales. This study of 'slump structures' enabled him not only to point to the origin of the structures themselves, but also led him to use the detailed patterns in the sediments to interpret the general arrangement of land and sea during the time of their formation. The results of this study have revolutionized the views concerning the growth of the Welsh Palæozoic geosyncline.

In recent years he has published the results of a life-long study of the plateau surfaces of the Welsh mountain areas and traced their origin far back into geological time, thereby giving a firm foundation to the theories advanced by others concerning the river systems of Wales and the West Country.

His best-known work centres on his native Wales, but much of it also deals with more general topics, and of recent years he has taken much interest in the geological interpretation of geophysical results, where his wide knowledge of structural geology has enabled him to assess the value of the interpretation made by the geophysicists.

Wherever his researches have taken him, he has broken new ground and led the way to new lines of research.

Davy Medal : Prof. R. D. Haworth, F.R.S.

Prof. Haworth, over a period of some thirty-five years, has made outstanding contributions to the chemistry of natural products, particularly the alkaloids.

His first important work was on the isoquinoline synthesis of alkaloids in the aporphine, berberine and related groups. Later he extended his synthetic work on the aporphine group of alkaloids and in particular synthesized morphothebaine methyl ether, which was a connecting link between the thebaine and morphine groups of alkaloids.

In association with G. R. Clemo, he successfully synthesized a number of degradation products of santonin, and then with various pupils, particularly at Sheffield, he studied many natural pigmented compounds of high molecular complexity, notably retene and the phenolic resins which constitute the lignan group of natural products. Purpurogallin yielded up the secrets of its structure to him and he was able to synthesize this interesting compound in 1949. His discovery that it contained a tropolone ring led him to engage in tropolone chemistry, in which field he has made significant contributions, particularly to the study of novel substitution reactions. He has conducted valuable researches in the complex steroidal group of alkaloids, especially on conessine, he has investigated the fundamentals of the reaction of formaldehyde with proteins, and he has carried out numerous synthetic studies on a variety of complex nitrogen-containing natural compounds.

Darwin Medal : Dr. J. S. Huxley, F.R.S.

Dr. Julian Huxley has left his mark in a number of varied fields of biological science. His concept of the cline proved of such value in the description and understanding of geographical variation, in both its genetical and ecological aspects, that it passed almost immediately into very wide use. He was one of the pioneer students of courtship behaviour in birds; indeed, in his classical paper on the great crested grebe he gave the first descriptive analysis of mutual display and introduced the notion of mutual selection. He has contributed to the evolutionary study of behaviour and to the theory of sexual selection. He has given us the idea of allæsthetic selection and has defined allometry or heterogonic growth as it is variously called. His investigations of heterogonic growth in a variety of animals brought to light the existence of allometric gradient fields, the evolutionary implications of which he pointed out. His early genetical investigations of *Gammarus* led him to appreciate the evolutionary significance of rate genes, and he has recently discussed the significance of polymorphism, or morphism as he prefers to call it.

Yet to many his greatest work will have been the part he has played in the development of the neo-Darwinian theory of evolution, of which he was indeed one of the earliest exponents. He is one of a number of biologists who have contributed in their various ways to this development, by experiment, mathematical analysis and theoretical discussion. Huxley has a place all to himself in that his wide nterests, encyclopædic knowledge, and ability to see the connexion between widely separate fields, have enabled him to bring together and bind into a single evolutionary thesis the findings of the most diverse branches of biology. He has been one of the leaders n the rise of modern evolutionary biology, and a never-failing stimulus to those who have come into contact with him in this field.

Hughes Medal : Viscount Cherwell, P.C., C.H., F.R.S.

Lord Cherwell's earliest papers are mainly connected with specific heats at low temperatures, but nclude many contributions on such varied items as radiation pressure applied to cosmic problems, the transmission of X-rays and the structure of atoms and nuclei, including an approximate quantitative theory of the Geiger–Nuttall relation. His work on he solid state led to the well-known melting-point formula. In this connexion he began to take an interest in the photoelectric effect, connecting the frequency of the selective effect in the alkali metals with the characteristic frequencies, the latter being calculated either from the melting-point formula or by 'Rest-Strahlen' determinations.

During the First World War he worked at the Royal Aircraft Establishment. There he learnt to ly, and his main interests were concerned with the nstruments of flight and with the problems of flight tself. He produced many technical papers in a wide range of subjects, including those on the theory of ompasses, on the collision of aircraft with balloon-barrage cables, and on the conditions which caused ertical spin in aircraft in flight and the methods of extraction of the machine from spin when involved either accidentally or deliberately in such a manœuvre.

After the War he devoted himself in Oxford to the reorganization of an obsolescent department into the important laboratory it is to-day. Perhaps his most important direct contribution to physics was his pioneer work with Prof. G. M. B. Dobson on meteors, which led by means of calculations of the height, frequency and the temperatures of the trails to a considerable increase in our knowledge of temperature distribution in the upper atmosphere, particularly the increase in temperature above the stratosphere. The latter was satisfactorily explained by the absorption of radiation by a layer of ozone. Further work was done on photoelectricity, mainly in connexion with its application to the determination of temperature, both in stars and in terrestrial sources, work which included the design of the well-known Lindemann electrometer. He has always been interested in astrophysics and cosmic phenomena, and has written many notes on these subjects. In particular, he has suggested the origin of magnetic storms as due to the recombination of electrons and ions in the upper atmosphere which arise from ionized clouds of gas ejected from the Sun, the velocity of the particles in the cloud being ascribed to light pressure.

In the Second World War he acted as scientific adviser to Sir Winston Churchill and produced a large number of reports and appreciations, many of which are mentioned in Churchill's book "The Second World War".

SOME INTERACTIONS OF THE PHYSICAL AND THE BIOLOGICAL SCIENCES

The citations which have just been read leave no anxiety about the importance of the contribution which Fellows of the Royal Society make to the improvement of natural knowledge. In hearing them we may perhaps feel that passing regret which we experience on a journey when some fascinating vista opens at a new turn of the route, and we are moved by the desire to explore it while realizing that we never shall. We are swept onward about our own business.

People often think nostalgically of the early days of this Society when all the Fellows could understand everything that went on. Range and diversity were, however, available at the price of superficiality and incoherence when even Newton seems to have felt that his view of Nature consisted after all of a series of very imperfectly related parts. To-day the whole has more structural unity, yet often seems so vast and labyrinthine that we get lost if we venture beyond our own small locality, which itself reveals subtleties and complexities multiplying almost without limit the more closely we look.

The process of elaboration, though deplored in one quarter or another almost daily, is not quite irreversible. As in all the great movements of Nature or of humanity, there are opposing tendencies and compensating reactions. On one aspect of this matter I shall dwell a little now.

At one time the segregation of the physical and the biological sciences could scarcely have been more complete. It is reflected indeed in the dichotomy of the Royal Society itself. The lines of demarcation are gradually vanishing, and our duplex structure is becoming something of an anachronism.

The fusion is occurring in many places: the interpretations of nerve action in terms of ionic flow, and of cortical events in terms of spatio-temporal patterns of neuronal activity; the analogies between the working of the brain and the operations of electronic calculators; all these and many more have for a long time compelled the simultaneous study of widely different fields of science.

It is difficult to think oneself back to the time when the preparation of urea from ammonium cyanate caused something of a sensation in the world. In his "Essays on Historical Chemistry" Thorpe wrote: "That particular day in 1828 when Wöhler first observed the transformation of ammonium cyanate into urea should be accounted a red letter day in the history of science".

Things have moved since then; structures have been determined and syntheses achieved for every kind of vital product from the anthocyanins of flowers to the adenosine triphosphate which so subtly regulates the energy exchanges in the cell. A year or two back the pituitary hormone oxytocin was synthesized by du Vigneaud and his collaborators, and the synthesis of another peptide pituitary hormone has been announced this year. Steroids are the object of unremitting and successful work in several laboratories, and nucleotide coenzymes continue to yield to the investigators of Todd's school, the total synthesis of cozymase having recently been carried out.

The relation of molecular structure to properties is a major chapter of science and now forms a body of doctrine built up over a century. Through the stimulus, partly industrial, of the intensive work on polymers—those huge molecules now made almost to a predetermined specification of properties—this study to-day embraces some of the chief constituents of the living cell.

Natural compounds of very high molecular weight, formed at low temperature and under the directing influence of existing cell structures, have normally a much more regular configuration than the chains randomly formed in polymerizations initiated by free radicals at high temperatures. The gap between the natural and the artificial has been significantly narrowed by the recent discoveries of Ziegler and of Natta. By the use of new catalysts based upon aluminium alkyls and titanium or vanadium chlorides, beautifully oriented polymers of regularly repeating structures are formed. The initiation mechanisms may well be ionic, and the regularity is almost certainly due to the guiding influence of a heterogeneous catalyst.

The closer approach of this mechanism to that used in the cell is very suggestive. Substances closely resembling natural rubber and guttapercha (which stand in a *cis-trans* relation to one another) have indeed been made by such means. The properties of these regularly ordered polymers are profoundly different from those of the less ordered forms, and during this year Natta, Corradini and Dall'Asta, in a study of crystalline polypropylene oxide, comment on the notable analogies between their product and the fibroin of silk.

In this general connexion the recent work of Ballard and Bamford is highly suggestive. These authors find that in the polymerization of DL-phenylalanine-N-carboxy α-amino-acid anhydride initiated by polysarcosine dimethylamide, the polysarcosine chain is able to catalyse the reaction between the base and the anhydride in a marked degree. They justly point out the analogy between this phenomenon and an enzyme reaction.

Work continues in many laboratories on the fibrous and globular proteins and on nucleic acids (and models have recently been shown to the Royal Society of the beautiful structures which the X-ray crystallographers are beginning to propose for these vitally important substances).

The problem is enormously complicated, but its attraction depends, of course, largely upon the belief, widely held on good grounds, that these structures are fundamentally concerned in the processes of heredity. Nevertheless, the view that nucleoproteins are the basis of genes which could ever be self-replicating in isolation and merely in virtue of their structure is probably a dangerous over-simplification.

In the chemistry of inanimate Nature the study of structure alone is quite insufficient, and must be undertaken in conjunction with that of function; in other words, reaction mechanisms are as important as molecular structures.

That the properties of living things are an emergent result of contributions from finite, if large, numbers of structural units or genes, that the genes are rather stable though not immutable, that in proper circumstances they change their associations in accordance with the laws of probability, are among the major basic principles of science. Recent work has, however, widened the view of the ways in which hereditary characters are transmitted. Besides sexual unions there are transmission by infective agents, by transduction and by Pontecorvo's parasexual mechanisms. Moreover, the combinatory phenomena that are so important in the Mendelian system cannot play much part in micro-organisms which multiply by binary fission. Fruitful as the reference of cell properties to the structure of genes has been, the body of doctrine which rests on this assumption is in some important respects incomplete, as indeed every chapter of science must be incomplete by itself. The picture presented is essentially static. The phenomena of growth, adaptation and reproduction need a dynamic one.

No one structure is likely to be autosynthetic in isolation; even the viruses require as hosts more or less intact cells, the machinery of which they can exploit. The building blocks of the cell, wonderful though they may be as structures, are useless by themselves. Cell function depends upon the rhythm and harmony of their reciprocal actions: the mutual dependence of protein and nucleic acid; the spatial and temporal relations of a host of elementary processes which with their sequences and bifurcations make up the reaction pattern of the cell. A system of mutually dependent parts, each of which performs something like enzymatic functions in relation to another, will, as can easily be shown, in the steady state appear as a whole to be autosynthetic. No individual part need be credited with a new and mysterious virtue by which to duplicate itself. Thus the picture widens beyond the structural units to their quantitative proportions, to their reciprocal dependence and to their rates of growth. This fusion of physical chemistry and biology leads to conclusions about the nature of adaptive processes, the automatic attainment of maximum growth-rates, and mechanisms for the choice of the most favourable metabolic patterns (as in the Pasteur effect).

The reality of the dynamic picture is sometimes called in question because there may be alternative explanations of particular phenomena. For example the important phenomenon whereby drug resistance develops is often referred exclusively to selection of random mutants, although it is easy to show on the basis of very general physico-chemical assumptions that the effect should demonstrably occur as an automatic response, the adapted cells having reorganized their reaction patterns. This conclusion in its turn in no way denies the possibility of spontaneous resistance due to structural mutations. Nor, on the other hand, does the occasional demonstration of mutations leading to resistance rule out automatic cytoplasmic adjustments.

One possible prescription for steering between the opposite hazards of narrowness and of superficiality is to try to set the particular objects of one's own interest into a general framework, working with a large map but filling in small areas with as much detail and accuracy as possible. Partly on this principle, but also, I confess, a little to vindicate my feeling that a president of this Society, whatever his other preoccupations, has the right and duty to remain a working man of science, I am proposing to devote a few paragraphs to some matters, relevant to the general theme, but closely connected with one of the fields of my own activity.

Resistance to the idea that some biochemical adaptations of cells are due to automatic internal reorganization has been largely founded on the relative stability of such changes, and upon the doctrine that heredity only changes by spontaneous gene mutation. Evidence, however, accumulates that adaptive processes are indeed reversible. *Aerobacter aerogenes*, once it has acquired the power of utilizing D-arabinose (A^+ character), holds it for a long time, but some strains of *Escherichia coli* revert rather quickly. Cross found that with *Aerobacter* loss of the A^+ character occurred more rapidly in certain media which themselves imposed a new adaptive necessity on the cells. The effect might have been attributed to a re-selection in these media of a small residual contamination of A^- (or of reverse mutants); but this explanation was ruled out by comparative experiments with artificial mixtures of the A^+ and A^- types. The real reversion of the population in conditions not favouring the selection of the A^- cells showed that arguments based upon the assumed permanence of the change are inadmissible.

The impression that drug resistance is a necessarily stable character is weakened still further by the study of micro-organisms other than bacteria. Wild found that with strains of *Saccharomyces cerevisiae* the degree of persistence of adaptation to various inhibitors is very variable.

Other evidence bearing on the nature of the adaptive changes responsible for drug resistance comes from the detailed study of time–number relations in colony formation on agar plates containing an inhibitory substance. If, say, 10^8 cells are plated on a solid medium containing a drug at a suitable concentration, there may appear 10–100 well-developed colonies which have been widely regarded as spontaneous mutants. But if the statistical distribution of the times at which they appear is compared with that for a correspondingly small number of cells previously adapted to resist the drug, then the comparison shows that the few survivors from the unadapted strain have formed colonies much more slowly than the members of the adapted strain. Individuals of this latter could therefore not have been present in the original even in the minute numbers supposed. Results of this kind have been found by Wild with yeast and by Dean with some bacterial strains. In some of these examples, moreover, the non-existence of minute numbers of the adapted forms in the original population is demonstrable even when the standard of resistance studied is quite a low one. Thus alternative explanations based upon complex series of multiple mutations would be forced to include highly unlikely assumptions.

One method by which pre-existent mutants are often tested for may be illustrated in the example of the well-known *Bacterium coli mutabile*. This organism normally refuses to grow on a lactose-agar plate except after a long delay. If, however, a very large inoculum of cells of the order 10^8 or 10^9 is plated, some colonies develop much more rapidly, and their number has been used to give a measure of the mutation-rate to the so-called lactose-positive condition.

Dean undertook a study of the statistics of colony formation by this organism on lactose-agar plates, measuring the distribution of colony sizes at various times, and the distribution of the times required for the formation of colonies of various standard sizes. The results conformed rather closely to Gaussian distributions, and the relatively few early-forming large colonies which might have been labelled lactose-positive mutants did not seem to be more frequent than the Gaussian law could permit in so enormous a population.

All these observations support the view that the cell makes adaptive changes by dynamical adjustments as well as by any mutations which it may suffer.

Normally, mutations, apart from those caused by radiation or special chemical agents, have been supposed to occur only when cells divide. This view itself seems to be changing.

Some years ago, Baskett made a number of observations individually and collectively indicating that during the long delay which attends the first growth of *Bact. lactis aerogenes* on D-arabinose there is in fact a physiological adaptation of the cytoplasm, and not the selection of mutants. Generally similar results have been found by Dean for cells initially reluctant to use lactose.

Somewhat analogous observations in a more spectacular form were reported by Akiba, and more fully by Szybalski. Bacterial strains exposed to streptomycin for a number of days in a buffer not supporting growth were found eventually, if they had survived at all, to have become resistant to the antibiotic. Szybalski, however, quotes what he calls "tentative evidence" that the changes occur in a nucleus. This evidence is derived from observations on the crossing or transduction phenomena which occur with certain strains of *Escherichia coli* and *Salmonella*.

The conclusion, however, seems to be far from certain, since the relations found in crossing drug-resistant with sensitive organisms are usually very complex. In genetic analysis with micro-organisms the number of parameters which can be adjusted is considerable, and illusory effects of sharp segregation phenomena are sometimes produced by the process of dividing continuous variables such as rate or time of growth into arbitrary domains such as 'slow' and 'fast' or 'plus' and 'minus'. That a high percentage of non-dividing cells should suffer nuclear mutations making them resistant precisely to that drug to which they are being exposed seems much harder to explain than the alternative of a dynamical change by which the cell as a whole reacts to the presence of the drug in an almost predictable way. The same general comments might be made about the 'spontaneous mutations' in the absence of division, to histidine-independence of a bacterial strain recently studied by Ryan.

In spite of some alarm, physico-chemical mechanisms of cell adjustment need not be in any conflict at all with valid principles of genetics. But it is a misapplication of the latter when they are used to exclude all mechanisms except selection of random mutants or of favourable gene combinations. Random mutations to drug resistance may indeed be shown by the relatively rare examples where the Lederberg technique of replica plating has given positive results. Nature, however, presents us with a vast hierarchy of systems: sub-atomic units (in a vast and confusing array), atoms and molecules, micelles, chromosomes, nuclei, cells, colonies, tissues, individuals and communities of individuals. Nobody can suppose that all phenomena have their origin at any one particular level.

In the organisms studied by classical genetics, individuals develop from fertilized germ cells, and, not surprisingly, show characteristics largely inherent in those cells. In micro-organisms which multiply by binary fission, the new individual does not develop from a much smaller germ cell but is formed by the approximate halving of an existing one, and, no more surprisingly, shows the characteristics of this. The manifestation of the effects of genes has long been recognized to be profoundly affected by their environment, so that the subsequent growth of the divided daughter cells is largely governed by the total organization. This explains—and more specific physico-chemical illustrations can be given—why such characters as drug resistance due to enzymatic reorganization can persist through many divisions. But to call the phenomenon or its interpretation Lamarckian is a plain misuse of language.

The disentangling of the complicated and fascinating relationships met with in this field will demand close co-operation of the physical and biological sciences, which brings me back to the keynote of this address. To the highly ingenious models of structure must be added equally illuminating models of function. Whatever the answer may be to the controversial problems of to-day, that is what the future in one way or another will surely bring forth.

OBITUARIES

Prof. Winifred Cullis, C.B.E.

By the death on November 13 of Prof. Winifred Cullis the world has lost not only a fine scientist but also an outstanding personality.

Winifred Clara Cullis was born in Gloucester on June 2, 1875. King Edward VI's High School for Girls, Birmingham, and Newnham College, Cambridge, laid the foundation of her abiding interest in science and began many life-long friendships. In 1901 she was appointed demonstrator in physiology at the London (Royal Free Hospital) School of Medicine for Women; later she became lecturer, reader and head of the Department, and finally professor of physiology in the University of London. She retired during the Second World War.

From the beginning, research was Prof. Cullis's great interest, and her name will always be associated with two outstanding pieces of work, one on the mechanism of the secretion of urine and the other on the perfused isolated heart of rabbit. Her experimental technique was precise and careful, and it was a joy to see the delicacy and sureness with which she would snip sufficient of the auriculo-ventricular bundle in the beating heart in order to demonstrate the effects of partial heart block. In later years lectures at home and abroad made continued research work more difficult; but periodically she would give herself a 'holiday' and with one or more colleagues settle down for several weeks investigating some interesting problem. She gave unstintingly of her knowledge and wide experience to her departmental colleagues but always insisted that publications should be in their own names, and any appreciation of their work gave her great pleasure.

No one who knew her could be other than filled with admiration for the absolute integrity and shining honesty which characterized her scientific outlook and the public work which later claimed so much of her time. For self-seeking, pomposity or hidden motives she had no use, and nothing was more direct than her own approach to a problem.

This directness, together with her gaiety and wit, made her lectures and speeches unforgettable. She had a store of appropriate stories—often against herself—and it was seldom that a speech of hers was not punctuated by laughter.

She herself realized how valuable were her special gifts as a speaker, and she gladly spoke for any cause she had at heart, particularly where she felt she could assist in securing for professional women equal opportunity and status with men. Her great charm was to a large extent due to her intense interest in and understanding of her fellow men and women. This and her generous appreciation of the other person's point of view, even when she disagreed, was particularly valuable in international contacts. In her work for the British Federation of University Women and for the International Federation of University Women, in each of which organizations she held the presidency for a number of years, she combined her interest in the advancement of women and her belief in the great value of international understanding and good will

Of the many honours and marks of appreciation that came her way, few gave Prof. Cullis greater pleasure than the decision of the British–American Associates to name one of their lecture fellowships after her.

She felt strongly that physiology should be taught in the schools and gave a series of most successful talks in the B.B.C. Schools Programme. She wrote two excellent books on the subject for use in schools. "Your Body and the Way it Works", published in 1949, is a very clever blending of her text with pictures by Ian T. Morison. Included is a section on growth, reproduction and heredity which is an aspect of human biology normally omitted from elementary books.

Few women could have had so many friends. She collected them from a world-wide circle. Her memory for them was amazing, and she would call to mind details about people she had not met for years and with whom she could have had the briefest conversation.

The loss of Winifred Cullis leaves a void in the lives of those who knew her, not only because she was a unique personality but also because of the deep affection she inspired.

M. BOND

Dr. A. L. Clark

IT was with a sense of genuine sorrow that the many friends of Dr. Arthur Lewis Clark learned of his death on September 20 at Kingston, Ontario, at the age of eighty-three.

Dean of the Faculty of Applied Science at Queen's University, Ontario, for twenty-four years from 1919, an outstanding physicist in research, Dr. Clark had retired in 1943, but continued to lead a full and active life until a short illness before his death. Dr. Clark was born on February 19, 1873, at Worcester, Mass., where he was educated, going to the Polytechnic Institute, where he obtained his B.Sc. degree. After doing his graduate work and some teaching, he went to Queen's University in 1906 as head of the Physics Department.

Dr. Clark's scientific interest was in thermodynamics and he carried out considerable research in this field. In 1916 he was appointed chairman of the University Scientific Research Committee. His recommendations with regard to the support of research at that time were far-reaching and established standards worthy of acceptance by any university to-day. In 1919 Dr. Clark was appointed dean of the Faculty of Applied Science, a post which he held until his retirement in 1943.

Retirement did not mean idleness to Dr. Clark, for one of the first tasks he set his hand to was writing his own now famous Queen's document, his book "The First Fifty Years", a history of the Science Faculty of Queen's from 1893 until 1943. The book filled a blank in the University records and has been enthusiastically received by graduates of all faculties.

During these twenty-four years there was war and depression, bringing great stress and strain to the University. Nevertheless, under Dean Clark's wise and efficient guidance, the standards of work in the various branches of engineering were more than maintained and the School of Applied Science grew to maturity. Dean Clark's firmness, tempered with patience and sympathy, won the esteem of staff, graduates and students alike.

In compiling the above note, I am indebted to Mr. David G. Dewar for information from his book, "Queen's Profiles", published by the office of Endowment and Public Relations, Queen's University.

H. G. CONN

NEWS and VIEWS

International Meteorological Organization Prize : Dr. H. T. Hesselberg

DR. HANS THEODOR HESSELBERG, formerly director of the Norwegian Meteorological Institute and president of the International Meteorological Organization, has been awarded the International Meteorological Organization Prize. This Prize was created by the World Meteorological Organization to perpetuate the memory of the non-governmental international organization which that specialized agency of the United Nations has succeeded. It is to be presented once a year in recognition of scientific contributions to meteorology and work for international meteorological organizations. Dr. Hesselberg, who has received the first award, was born at Lierne in Norway in 1885, and has devoted himself from 1912 onwards to meteorological and hydrological research. As scientific assistant to Dr. Bjerknes, he participated in research in the fields of dynamic meteorology and hydrology. He was director of the Norwegian Meteorological Institute during 1915–55. During these forty years he was mainly concerned with the organization of the Meteorological Service of Norway and international co-operation. From 1919, he took an active part in the work of the International Meteorological Organization, of which he was president during 1935–46. Dr. Hesselberg was a member of the executive committee of the World Meteorological Organization during 1951–55.

Mathematics in the University College of North Staffordshire : Prof. D. S. Jones, M.B.E.

MR. DOUGLAS JONES, who has been appointed to the chair of mathematics in the University College of North Staffordshire in succession to Prof. I. N. Sneddon (see *Nature*, 177, 1109 ; 1956), was educated at Wolverhampton Grammar School, and went up to Corpus Christi College, Oxford, with an open scholarship in 1940. Soon afterwards, however, he joined the R.A.F., becoming attached to night fighters as a signals radar officer. In 1942 he was put in charge of a special research unit, and for his work in this capacity was mentioned in dispatches and later made M.B.E. In 1945 he returned to Oxford, where he took first-class honours in mathematics two years later. Then he went with a Commonwealth Fund fellowship to the Massachusetts Institute of Technology, where he started his researches on wave diffraction theory. This has continued to be his major research interest ; but the power and complexity of the mathematical methods he has brought to bear on it have never been allowed to obscure in Jones's mind, nurtured alongside the pressing needs of war-time radar, the many practical applications of the results of his calculations. In 1948 he returned to England as an assistant lecturer in the Mathematics Department in the University of Manchester, where he was promoted to lecturer in 1951 and to senior lecturer in 1955. He has held the responsible position of tutor to the Faculty of Science since 1954, and while on leave of absence for six months in 1955 was a visiting research professor at the Institute of Mathematical Sciences, New York University. His most recent interest is a fundamental study of methods for calculating short-wave scattering.

British Cotton Industry Research Association : Dr. G. F. Davidson

DR. G. F. DAVIDSON, of the British Cotton Industry Research Association, head of the Chemistry Department at the Shirley Institute, Manchester, is resigning his post at the end of this year, though he will remain in the service of the Association. Dr. Davidson has already served for thirty-four years on the scientific staff of the Association. Much of this time was occupied by studies of the chemistry of cotton cellulose, and his contributions to this subject are widely recognized. At the beginning of his investigations, the modern concepts and theory of cellulose structure were only just emerging. He used the new concepts to correlate a large body of otherwise confusing experimental observations. In doing so, he helped to establish the theory; and, in seeking a theoretical explanation of certain practically important observations, he uncovered fresh facts stimulating theoretical investigations in a more general field.

Dr. J. Honeyman

DR. J. HONEYMAN, lecturer in organic chemistry at King's College, University of London, has been appointed to succeed Dr. Davidson at the Shirley Institute. Dr. Honeyman's work has also been mainly in the field of carbohydrate chemistry. He graduated from the University of St. Andrews in 1939 and obtained his Ph.D. from that University in 1944. After spending a number of years in industry, Dr. Honeyman was appointed assistant lecturer at King's College, London, in 1945, and lecturer in 1947. He has contributed many papers, chiefly concerned with carbohydrates, and in 1948 published an "Introduction to the Chemistry of the Carbohydrates", of which a revised edition was published in 1951. During 1954–55 Dr. Honeyman held the post of Hibbert Fellow at McGill University, and was visiting scientist at the Pulp and Paper Research Institute of Canada.

Royal Society: Officers and Council

AT the anniversary meeting of the Royal Society held on November 30, Sir Cyril Hinshelwood was re-elected president. Sir William Penney, director of the Atomic Weapons Research Establishment, Aldermaston, was elected treasurer in succession to Sir Thomas Merton. The other officers re-elected for the ensuing year were: Physical Secretary, Sir David Brunt, chairman of the Electricity Supply Research Council of the Central Electricity Authority; Biological Secretary, Prof. G. L. Brown, Jodrell professor of physiology at University College, London; and Foreign Secretary, Dr. H. G. Thornton, head of the Department of Soil Microbiology at Rothamsted Experimental Station. Other members of the Council elected were: Prof. C. E. H. Bawn, professor of inorganic and physical chemistry, University of Liverpool; Prof. T. A. Bennet-Clark, professor of botany, University of London (King's College); Brigadier J. S. K. Boyd, lately director of the Wellcome Laboratories of Tropical Medicine; Dr. Mary L. Cartwright, mistress of Girton College and university lecturer in mathematics, Cambridge; Prof. N. Feather, professor of natural philosophy, University of Edinburgh; Sir Claude Gibb, chairman and managing director of Messrs. C. A. Parsons and Co., Ltd.; Sir Bryan Matthews, professor of physiology, University of Cambridge; Prof. J. S. Mitchell, professor of radiotherapeutics, University of Cambridge, and director, Radiotherapeutic Centre, Addenbrooke's Hospital, Cambridge; Prof. W. T. J. Morgan, deputy director of the Lister Institute and professor of biochemistry, University of London; Prof. N. F. Mott, Cavendish professor of experimental physics, University of Cambridge; Prof. L. Rosenhead, professor of applied mathematics, University of Liverpool; Dr. B. F. J. Schonland, deputy director, Atomic Energy Research Establishment; Dr. K. M. Smith, director of the Virus Research Unit (Agricultural Research Council), Molteno Institute, University of Cambridge; Prof. M. Stacey, professor of chemistry, University of Birmingham; Dr. W. H. Thorpe, university lecturer in entomology, Cambridge; Prof. L. R. Wager, professor of geology, University of Oxford.

International Journal of Applied Radiation and Isotopes

THE new periodical, the *International Journal of Applied Radiation and Isotopes*, published by Pergamon Press (London and New York), is to provide a medium for the publication and discussion of radioactive and radiation techniques and the applications of radioactive isotopes and large fluxes of radiation in the pure and applied sciences, medicine, agriculture and industry. The subscription is £6 (17 dollars) or, for individual subscribers certifying that the journal is for their private use, £3 10*s*. (9.80 dollars). The list of nine editors, headed by P. C. Aebersold (Oak Ridge, U.S.A.), which includes eminent scientists from France, Holland, Great Britain, the Netherlands and the U.S.S.R., and the editorial advisory board which consists of representatives from thirteen different countries, emphasize the international character and high standard of the new periodical. Sir John Cockcroft, one of the United Kingdom representatives of the board, contributes a brief editorial to the first number of the *Journal* (pp. 144; July 1956), and W. B. Mann (U.S. National Bureau of Standards) is the author of the leading article, entitled "The Preparation and Maintenance of Standards of Radioactivity", in which he gives a historical survey of the preparation and measurement of international radium standards and explains the need for standards of other radioisotopes. A report is given of the present state of international comparison of several radioisotopes, and a policy for wider international comparison is discussed. There are nine other original articles dealing, respectively, with radioactive tracer techniques for sand and silt movements under water, particularly the use of powdered glass containing scandium-46; a radiochemical technique for determining the surface area of aluminium metal surfaces; liquid scintillators; labelled metabolic pools for studying the biochemistry of toxic action; the behaviour in the rat of plasma proteins labelled with carbon-14 and iodine-131; the production and clinical application of iodine-132; autoradiography; gamma-ray vulcanization of rubber; and an impulsion discriminator for activation analysis. The number concludes with the titles and abstracts of the papers presented to the third annual meeting of the Society of Nuclear Medicine, held during June 21–23 at Salt Lake City, Utah.

Automation Progress: New Journal

'AUTOMATION' is an ill-defined word which no one likes and everyone uses. For the past three years, however, it has been a very live topic, and, as a result, existing journals have tried to persuade their readers that they cover at least a part of automation, and new journals with automation in the title have been appearing at frequent intervals in Europe as well as North America. The latest such periodical is *Automation Progress: The Journal of Automatic*

Production and Control, a monthly publication, the first number of which appeared last October (London: Leonard Hill Technical Group; 50*s*. a year). It is designed to fill the gap between highly specialized publications and the general technical press, in order to meet a long-felt need for a means of exchanging information between engineers and executives who have no time to follow the literature on any subject but their own. The first two numbers contain a number of interestingly written articles on problems of the automatic factory, and a vast range of equipment is described. There are also short digests of relevant articles in other journals, and of relevant patent specifications accepted, notices of forthcoming events, an editorial, "news briefs" and a cartoon. The new journal, therefore, not only provides interesting material for higher management interested in automation, but also brings together a great deal of information useful to development engineers working in the field. The format and arrangement of material are both good, and it is noteworthy that the American practice of mixing up advertisements and text has been avoided. It must, however, be emphasized that the number of journals dealing with automation in one form or another is now so great that it is quite impossible for any one man to read them all, although the amount of new and useful information available is probably not more than could be covered by a single journal, allowing for cross-references to and abstracts of specialized articles in periodicals covering other fields. Eventually, therefore, there may be a marked reduction in the number of journals purporting to cover the field of automation, and, from the engineer's point of view, the sooner this happens the better.

Fisheries and Animal Husbandry in Japan

A LINKING of fisheries and animal husbandry may indicate a new and broadly based view of the development of natural resources or a 'marriage of convenience' possible only when traditional barriers have been removed by catastrophe. The University of Hiroshima established its Faculty of Fisheries and Animal Husbandry in 1949 at Fukuyama, on the shores of the Inland Sea and with a cattle-raising hinterland, and the Faculty began to issue a journal in 1955. From the first number it is difficult to visualize the proposed scope of work of the Faculty; its contents no doubt reflect the interests of staff rather than suggest an outline of its programme. T. Irie reports a study by X-rays and histochemical techniques of the crystal structure and texture of otoliths of the marine teleost *Pseudosciaena*; T. Fujiyama describes the life-history of and cytological studies on the monœcious plant *Prasiola japonica* Yatabe. Both these papers are in English. Y. Anagama contributes an extensive review, in German, of research on vitamin C in milk and milk products, in conjunction with the results of his own work. Two papers in Japanese, with brief English summaries, complete the number; of these the first, by S. Ono, describes the system and methods of selling calves by auction practised in Japan, while the second is a long account by M. Ikeda of "Studies on Properties and Agricultural Development of Alkali Soil in Manchuria", with numerous tables and text figures of which the legends are also in English, and 141 references of which only those of Oriental origin bear dates later than 1938. The journal is well printed and the illustrations, line drawings and plates, are clearly reproduced. In its present form and content it would seem more acceptable to central reference libraries than for circulation to specific interests; as an addition to the mass of literature in these fields it can be welcomed in so far as it gives a medium of publication for this group of workers.

Bulletin of Polish Medical History and Science

POLISH medical literature comprises at present no less than thirty-nine periodicals, but only a few of these reach medical men and scientists outside Poland. It is for that reason that the Polish Medical Alliance, an organization with editorial offices in Chicago, decided to "present to the English-speaking physician the outstanding research works, both past and present, along with a résumé of the accomplishment of Polish medicine". The first issue of the *Bulletin of Polish Medical History and Science* (Vol. 1, No. 1; July 1956. Pp. 48. Polish Medical Alliance, 2424 N. Kedzie Avenue, Chicago 47, Ill. 1.50 dollars) contains, apart from abstracts from numerous papers which appeared in Polish journals, three original articles, of which the first, on "Nicolaus Copernicus, Physician and Humanitarian", has been written by the chief editor, Dr. Alexander Rytel.

Alchemy and Early Chemistry

THE October issue of *Ambix, the Journal of the Society for the Study of Alchemy and Early Chemistry*, contains an appreciative obituary of the late Dr. F. Sherwood Taylor (who was editor from the inception of the journal in 1937) by the chairman, Dr. E. J. Holmyard. The new editor is Mr. D. Geoghegan. The number includes several interesting articles. The first, by Dr. Sherwood Taylor, is on the alchemical work of Isaac Newton and gives a transcription of a manuscript written by Newton which is apparently an attempt to form an intelligible body of doctrine from a number of quotations from alchemical authors, of which it mainly consists. Prof. Lynn Thorndike contributes a study of some alchemical manuscripts at Bologna and Florence. There are short articles on John Hariot's secret script by E. Seaton, and on J. B. Hunyades by Sherwood Taylor and C. H. Josten. An article on "Chymeutike, the real Hellenic Chemistry", by Procopios D. Zacharias, is a concise but detailed summary of publications by Prof. M. K. Stephanides, of Athens, which are otherwise available only in Greek. It attempts to put further back the beginning of chemistry, but is in error in saying that the famous Leyden Papyrus was found by Maspero (it was sold by collectors to Anastasy) and in dating it in the third century B.C. (it is dated by experts as A.D. 346). Stephanides suggested that the name 'chemistry' comes from the Greek *chymeia*, meaning 'preparing a *chyma*', and that the practice arose from the washing of auriferous sands in Egypt. The theory was based on old Greek philosophical ideas, Heraclitus and Democritus being connected with the development; the "Hellenic chymeutike has no connection whatever with Alchemy". Esoteric alchemy is represented in this number of *Ambix* by some reviews of books, including two on Lull, from the writings attributed (probably wrongly) to whom, it is said, much of English alchemical tradition seems to be derived.

Two Palæolithic Sites in Lower Austria

VOL. 7 of the "Mitteilungen der Prähistorischen Kommission der Österreichischen Akademie der Wissenschaften" (Vienna, 1954–55) contains an account of two palæolithic sites in Lower Austria, one near Kamegg in the Krems region and the other near Getzersdorf im Traisental. The former belongs to a very late palæolithic and can be grouped with the Hamburg series; the latter is rather older and can be classed as a late gravettian, so far as the upper levels are concerned, the lower level being somewhat older. Both sites are described by Dr. F. Brandtner, the actual description of the industries from Getzersdorf being by Dr. F. Felgenhauer. The illustrations of the tools found at Kamegg are excellent, those from Getzersdorf are indifferent. The whole forms a useful number with full descriptions of what are obviously important local sites.

Observations on the Size of the Sun

While numerous workers have claimed to have detected variations in the diameter of the Sun, other investigators have failed to find any variations, or to detect any significant differences between the equatorial and polar diameters. A paper entitled "Greenwich Observations of the Horizontal and Vertical Diameters of the Sun", by P. J. D. Gething, of the Royal Greenwich Observatory (*Mon. Not. Roy. Astro. Soc.*, 115, 5; 1955), gives the results of the yearly mean horizontal and vertical radii of the Sun observed at Greenwich from 1851 to 1939, but corrections for personality have not been applied. These are compared with observations for the horizontal semi-diameters of the Sun, made at Campidoglio since 1876, and later at Monte Mario; but there is no obvious agreement between the variations found at the two observatories. It has been claimed by Miss M. A. Giannuzzi, however, that the Greenwich observations of horizontal diameter contained an oscillation with a period of 22–24 years, agreeing in period and phase with an oscillation found from the Italian results, and a more detailed analysis of the Greenwich measurements of both horizontal and vertical diameters during 1915–36 was undertaken, in which allowance was made for the effect of personality and irradiation. The resulting diameters show that there were comparatively large variations from year to year; but it is emphasized that these variations do not necessarily represent real changes in the size of the Sun and may be due to variations in the mean personality correction. It is pointed out that Miss Giannuzzi's use of observations obtained by a large number of observers without applying personality corrections, on the assumption that changes in the mean personality corrections would be sufficiently small to be ignored, may not have been justified. A table in Gething's paper, which gives the horizontal semi-diameters corrected for personality, in the observations during 1917–36 by five members of the Greenwich staff, shows that the scatter around the combined mean of the individual means, when corrected for personality, is so large that the reality of the variations from year to year is untrustworthy. From the relative sunspot areas during 1917–36, it is seen that there is no obvious connexion between sunspot activity and the apparent variations in diameter. The conclusion is that Greenwich observations do not provide any clear evidence of real variation in the size of the Sun.

Growth of Isolated Oat Embryos

In an investigation of amino-acids as sources of nitrogen for the growth of isolated oat embryos, G. P. Harris (*New Phytol.*, 55, 2, 253; 1956) has found that ammonia, nitrate and casein hydrolysate were each effective as nitrogen sources. Casein hydrolysate was not inferior to the inorganic forms of nitrogen. A mixture of eighteen of the amino-acids present in casein hydrolysate was able to substitute for the latter as a nitrogen source for the growth of the embryos. The value of the mixture of amino-acids as a nitrogen source was dependent on interactions occurring between its constituent amino-acids. Out of twelve of the latter, all except arginine were markedly inhibitory to growth in length of the roots, when supplied alone. Marked antagonisms occurred between L-phenylalanine and L-tyrosine, DL-isoleucine and DL-valine, L-leucine and DL-valine, and L-arginine and L-lysine in their effects on root growth. Amino-acids which alone produced no, or relatively little, inhibition of root growth generally antagonized the effects of amino-acids which were more inhibitory.

Geographical Association: Annual Meeting

The annual meeting of the Geographical Association will be held in the London School of Economics during January 1–4 under the presidency of Lord Nathan, who will speak on "Aviation and Geography: Reaction and Interaction". Among the topics to be discussed are: water supply in Britain (Prof. W. G. V. Balchin); techniques in field-studies (Dr. E. W. H. Briault); antarctic exploration (Mr. E. W. K. Walton); the International Geophysical Year (Dr. D. C. Martin); agricultural changes in the Chilterns (Mr. J. T. Coppock); economic development of Brazil (Prof. R. O. Buchanan); and geography and the social revolution (Prof. D. L. Linton). There will also be a discussion on "Geography and a Liberal Education". There will be the usual publishers' exhibition of books, maps and appliances, and exhibits of field-work, film strips, etc., by members of the Geographical Association. Further particulars of the meeting can be obtained from Mr. R. C. Honeybone, University of London Institute of Education, Malet Street, London, W.C.1.

Conference of the Universities of Great Britain and Northern Ireland

The annual conference of the Universities of Great Britain and Northern Ireland will be held in the Senate House of the University of London during December 14 and 15. The topics for the three sessions are: "Overloading Curricula and the Length of Undergraduate Courses" (Sir Philip Morris, chairman of the Committee of Vice-Chancellors and Principals (*chairman*); Mr. R. B. McCallum, master of Pembroke College, Oxford; Prof. C. B. Perry, professor of medicine, University of Bristol; Prof. D. G. Christopherson, professor of applied science, Imperial College of Science and Technology, London); "Organization of Postgraduate Studies" (Dr. Constance M. Rigby, president of the Association of University Teachers (*chairman*); Sir James Mountford, vice-chancellor, University of Liverpool; Dr. D. A. Bell, Department of Electrical Engineering, University of Birmingham; Prof. F. S. Dainton, professor of physical chemistry, University of Leeds; Prof. E. R. H. Jones, Waynflete professor of chemistry, University of Oxford); "Impact on the Universities of the Government's Policy for the Expansion of Technological Education" (Dr. J. F. Lockwood, vice-chancellor, University of London (*chairman*); Sir Eric Ashby, president and vice-chancellor, The Queen's University, Belfast; Sir Harry Pilkington (*chairman*), National Advisory

Council for Industry and Commerce; Dr. Willis Jackson, chairman of the Joint Committee on the Supply and Training of Teachers for Technical Colleges). The conference is open only to delegates and to specially invited guests.

Christmas Lectures

The Christmas Lectures at the Royal Institution, Albemarle Street, London, W.1, will be given this year by Dr. H. Baines; the subject will be "Photography", and Dr. Baines is giving six lectures on Thursdays, Saturdays and Tuesdays, beginning December 27. At the Institution of Electrical Engineers, the Christmas Lecture for older schoolchildren will be given by Mr. J. F. Coales, of the Engineering Laboratory, University of Cambridge; he will speak on "Automation" and the lecture will be given on January 1 and repeated on January 2, at 3 p.m. Applications for tickets for Mr. Coales's lecture, which are free, should be sent to the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: N. Lawrence (scientific officer, Royal Observatory, Hong Kong), deputy director, Royal Observatory, Hong Kong; F. J. Parnell (assistant director, Game and Tsetse Control, Northern Rhodesia), director of Game and Tsetse Control, Northern Rhodesia; P. R. Adam, agricultural officer, Gold Coast; J. L. Anderson, agricultural officer, Western Region, Nigeria; M. G. Clough, agricultural engineer, Northern Region, Nigeria; R. Comber, agricultural specialist (plant physiologist), Gambia; P. G. Dennison, agricultural officer, Kenya; D. P. Drew, agricultural officer, Northern Region, Nigeria; W. M. Graham, entomologist, Maize and Produce Control, Kenya; F. N. Goodwin, agricultural officer, Northern Region, Nigeria; R. T. Harberd, agricultural officer, Northern Region, Nigeria; H. E. Hill, soil surveyor (Soil and Land Use Survey), British Guiana; S. P. Legg, livestock research officer, Ebini, British Guiana; K. R. Middleton, agricultural chemist, Northern Region, Nigeria; E. J. Mundy, agricultural officer, Northern Region, Nigeria; O. S. Swainson, principal, Farm Institute, Uganda; J. F. Ward, horticulturist, Department of Agriculture, Jamaica; R. B. Iles, scientific officer (zoologist), East Africa Fisheries Research Organization, East Africa High Commission; D. G. Almond, geologist, Uganda; H. P. J. Barr, assistant conservator of forests, Northern Region, Nigeria; P. B. Cruickshank, assistant conservator of forests, Gold Coast; R. M. Lee, assistant conservator of forests, Gold Coast; J. S. Scott, conservator of forests, Northern Region, Nigeria; O. Barnes, tsetse officer, Tanganyika; E. A. S. La Croix, entomologist, Tsetse Control Department, Gold Coast; P. L. Shinnie, director of antiquities, Ministry of Social Services, Uganda; B. Heyworth, veterinary officer, British Guiana; D. McManus, veterinary officer, Kenya; D. D. O. Pawson, veterinary officer, Tanganyika; J. H. Robb, veterinary officer, Western Region, Nigeria; L. F. Slater, veterinary officer, Uganda; R. C. H. Sweeney, section scientific officer, Nyasaland; W. Martin, senior technical assistant, Tuberculosis Research Unit, Gold Coast; P. Thomas, cocoa soil survey officer, Western Region, Nigeria.

Announcements

Sir Christopher Hinton, managing director of the Industrial Group, United Kingdom Atomic Energy Authority, has been awarded the Churchill Gold Medal for 1956 of the Society of Engineers, for his work on atomic energy.

Dr. William J. Robbins, director of the New York Botanical Garden and professor of botany in Columbia University since 1937, has been elected a trustee of the Rockefeller Institute.

Mr. W. A. Sanderson, an assistant director of the Nuffield Foundation, has been appointed secretary of the United Kingdom and British Commonwealth Branch of the Calouste Gulbenkian Foundation, which will be temporarily accommodated in Nuffield Lodge, Regent's Park, London, N.W.1.

The following appointments in the University of Sheffield have been announced: Dr. A. Critchlow, to be lecturer in chemistry; Dr. A. R. Entwisle, to be lecturer in metallurgy. Dr. P. H. Price, lecturer in fuel technology, has resigned.

The annual exhibition of laboratory apparatus and techniques arranged by the Manchester and District Section of the Royal Institute of Chemistry will be held in the College of Science and Technology, Sackville Street, Manchester, during 2 p.m.–8 p.m. on January 3 and 10 a.m.–8 p.m. on January 4.

The Education Panel of the Corrosion Group of the Society of Chemical Industry is offering a prize of 25 guineas for an essay or paper on any aspect (not necessarily research) of corrosion of metals and its prevention. Competitors must not be more than twenty-seven years old, and their contributions, which may contain diagrams and photographs, should be approximately four thousand words in length. Entries must be submitted before March 31 to the Corrosion Group Essay Competition, c/o Society of Chemical Industry, 14 Belgrave Square, London, S.W.1, from which further information can be obtained.

The Managing Trustees of the Drummond Fellowships for Research in Nutrition will consider in March 1957 applications for not more than one Drummond Senior Fellowship (£900 per annum) and not more than two Drummond Junior Fellowships (£500 per annum) for research in nutrition. The fellowships will normally be tenable for two years. Particulars can be obtained from the Honorary Secretary, Drummond Trust, University College, Gower Street, London, W.C.1. Completed application forms must be received not later than January 31, 1957.

Research papers on the chemistry and technology of oils and fats by a scientific worker in India are invited for consideration for the award of the Prof. T. P. Hilditch Medal. Such papers must relate to work carried out in the past two years, and should reach the convener of the award committee, Dr. D. R. Dhingra, H.B. Technological Institute, Kanpur, India, by December 31.

The British Steel Castings Research Association has moved to new laboratories at East Bank Road, Sheffield 2.

A review of "The Chemistry of Living Cells" by Prof. Helen R. Downes was published in *Nature* of November 24, p. 1140. We are informed that the English publishers are Longmans, Green and Co., Ltd., and the price is 45*s*. net.

NEW MAUNA LOA OBSERVATORY UNIT

By ROY L. FOX

Meteorologist in Charge, Pacific Area, U.S. Weather Bureau

A NEW high-altitude unit of the Mauna Loa Observatory to be used for observations and research projects was recently completed and dedicated. This unit, termed the 'slope' unit of the Observatory, is situated on the north slope of Mauna Loa at an elevation of 11,134 ft. above sea-level and is accessible over a gradual grade highway constructed of crushed lava and volcanic cinders. It is a companion unit to the much smaller and decidedly less accessible unit of the Observatory erected in 1951 at an elevation of 13,453 ft. near the summit of the mountain.

Its setting is the large volcanic mountain, Mauna Loa, often referred to as one of the largest single land masses in the world. The mountain comprises approximately half the island of Hawaii, the largest and south-easternmost of the Hawaiian Islands, and is noted not only for its massiveness but also for its very gradual slopes with almost constant grade. The 'straight line' average grade over a distance of approximately forty miles along the north-east slope from the summit, at 13,680 ft. above sea-level, to the sea in the vicinity of Hilo, the principal city on the Island, is less than 7 per cent. This is the slope traversed by the highway to the Observatory and also the one almost directly facing the prevailing quarter from which the trade winds in the vicinity of the Hawaiian Islands blow.

A trip up this highway to the 'slope' unit from Hilo carries one from a point near sea-level, where the average annual rainfall is 140 in., past the region of maximum rainfall near 3,000 ft. above sea-level, where it is more than 240 in., thence through a section of rapidly decreasing rainfall with height and then to the area from around 9,000 ft. to the Observatory unit, where the average annual rainfall is just under 20 in. The vegetation zones along the roadway serve as excellent climatic indicators and strikingly attest to these rainfall regimes. For the first 1,500 ft. or so of elevation the vegetation is predominantly shrub and closed forest. A dense tropical rain forest extends from around 1,500 ft. to near 5,500 ft. above sea-level, where vegetation begins to thin. Open forest then prevails for some distance, giving way to upland open shrub-type vegetation which, in turn, is replaced by a sparse growth of the primitive plant forms such as fungi, lichens and some mosses existing in the lava wastelands.

The 'slope' unit is housed in a pleasant one-story concrete block building, 20 ft. × 40 ft., partitioned into a 16 ft. × 20 ft. combination laboratory and workshop, three bedrooms and a combined kitchenette and dining room. There is also a ground-level concrete pad 15 ft. × 45 ft. for basing instruments, a raised wooden instrument platform and two instrument and antenna towers. It develops it own electrical power from its diesel-operated generating system. It also has its own radio communications link with the Weather Bureau Office in Hilo, an electrical lighting system and a water catchment and water storage and distribution units as well as a space heater, water heater, cooking range and refrigerator, all using butane.

The Mauna Loa Observatory is operated by the U.S. Weather Bureau, but at present it is not staffed on a fully continuous basis. Plans are, however, to have personnel regularly man the station and attend the instruments on four days of each week beginning in the very near future. For the remaining portion of each week, meteorological data will then usually be obtained, as they are now, by recording devices alone. However, for those periods when special research projects are being carried on at the Observatory by other groups through arrangements with the Weather Bureau, the meteorological instruments, along with other types of equipment, will be attended daily, and data on recorder records will be supplemented with visual data. Ultimately, if plans materialize, the Observatory will be staffed continuously, year in and year out.

The usual meteorological instruments, most with recording features, are now in use or soon will be in use at the Observatory. Data to be obtained on a continuous basis are wind speed and direction, pressure, temperature, humidity and rainfall. Additional data being anticipated for interrupted periods of several days per week are duration of sunshine, sky cover, cloud types and amounts, current weather and related features and pilot-balloon information. It is also expected that, when the Observatory is operated on a continuous basis, all these elements will be observed and/or recorded continuously, day in and day out, and that there will also be such additional measurements as those of solar radiation and ozone content of the air and that possibly some high-volume dust sampling and other dust measurements will be made.

Its accessibility, fine living accommodation and excellent provisions for basing instruments make this 'slope' unit particularly useful for special short-period projects. Other attractive features are its tropical location, its altitude—which is well above the usual height of the trade wind inversion in this tropical mid-Pacific area and which places it above much of the atmosphere's moisture and trade wind cumulus cloudiness most of the time—and its great distance from any large continental land masses and industrial areas.

The Observatory's high-altitude setting at a tropical location near the centre of the largest ocean on the globe makes it a unique facility. It is also less than a seven-hour trip from Honolulu, the travel hub of the Pacific, from which the first portion of the trip is by air to Hilo, thence up the mountain highway by motor-car.

One special project, namely, a series of spectrographic observations of the atmosphere of the planet Mars by a group of National Geographic Society scientists, has recently been completed at the Observatory. During the coming winter, it is hoped to study the structure of naturally formed snow crystals in an atmosphere with limited quantities of aerosols. Also arranged for next spring is a special study of solar radiation.

Preliminary negotiations for use of the 'slope' unit for a special project should be with the Chief of the Weather Bureau, by writing to the Chief of the Observations and Stations Facilities Division, U.S. Weather Bureau, Washington 25, D.C.

AFRICAN VEGETATION

MEETING AT YANGAMBI

THE study of natural vegetation, which has no regard for international boundaries, is of primary importance in the scientific development of Africa. It is therefore good to note that the Conseil Scientifique pour l'Afrique au Sud du Sahara, in conjunction with the Commission de Co-operation Technique en Afrique au Sud du Sahara, is now taking steps to promote international co-operation in this basic branch of science.

During July 29–August 8 this year a meeting of specialists in phytogeography was held in the Belgian Congo, under the presidency of Prof. J. Lebrun, secretary-general of the Institut National pour l'Étude Agronomique du Congo belge. The sessions were held at Yangambi, the African headquarters of the Institute, which is on the north bank of the Congo, about 90 kilometres downstream from Stanleyville, in dense evergreen rain forest. In 1885, H. M. Stanley wrote, "Yangambi is beautifully situated on a level terrace. The summits of the ridge appear to offer a charming field for European agriculturists". To-day the Institute's impressive organization at Yangambi employs some two hundred Europeans.

The member-governments of the two sponsoring bodies were represented by Prof. J. Lebrun (Belgium), Prof. J. Trochain (France), Dr. R. A. Dyer (Union of South Africa), Prof. P. W. Richards (United Kingdom), Dr. F. A. Mendonça (Portugal) and Prof. A. S. Boughey (Federation of Rhodesia and Nyasaland). The other participants were Prof. J. Millot, Prof. Th. Monod, A. Aubréville, Prof. R. Pichi-Sermolli, Dr. R. O. Whyte (Food and Agriculture Organization), R. W. J. Keay (sponsored by Unesco), and E. A. Bernard, Dr. R. Germain, E. Maudoux, R. Devred, L. Liben, C. Evrard and R. Gutzwiller, of the Institut National pour l'Étude Agronomique du Congo Belge.

In the field of plant taxonomy, international co-operation in Africa south of the Sahara is already well organized. The International Association of Plant Taxonomists and the Association pour l'Étude Taxonomique de la Flore d'Afrique Tropicale make important contributions towards this co-operation, the great national herbaria are in close contact with each other, and taxonomists—by and large—use much the same methods and concepts and accept comparable standards.

The position as regards plant ecology or phytogeography is, however, very different. There are, at the outset, considerable differences in the methods and concepts of the 'ecology' taught in British universities, largely influenced by Clements and Tansley, and the 'phytosociology' of the Braun-Blanquet school taught in most French and Belgian universities. The divergence has been aggravated by the fact that vegetation-mapping had been unfashionable in Britain during the past thirty years or so. British-trained botanists have, consequently, been going to Africa without much guidance on one of the first problems presented by African plant-life, so that ecological work has developed very individually in each territory. There is also a considerable difference, particularly outside the rain-forest regions, between the approach of the agriculturist who thinks of the vegetation as potential grassland, and that of the forester who thinks of the same vegetation as potential forest.

Much literature and many vegetation maps have been produced in recent years, but it is extremely difficult to correlate the work done by different authors, even in neighbouring African countries. The initiative taken by the Counseil Scientifique pour l'Afrique au Sud du Sahara in promoting international understanding in these matters is therefore most welcome.

The meeting at Yangambi was preceded by an interesting and well-organized excursion to the Haut-Uele Province in the north-east Belgian Congo. After examining forests near Stanleyville, the party travelled by air 350 km. north-east to Paulis. This important centre for *Coffea robusta* and cotton plantations lies in the rain-forest zone, and it was only after the party had travelled about 75 km. toward Dungu, that the first savannah vegetation was seen. All agreed that this vegetation and much of that seen on the journey (210 km.) next day to Aba had been derived from closed forest by man's farming and grass-burning activities; there was, however, a good deal of argument about the precise nature of the climax. Near Aba, the party saw a most interesting outlier of semi-evergreen rain-forest at Kurukwata, and later an example of the *Isoberlinia doka* woodlands, which are characteristic of a distinct belt stretching from French Guinea to Uganda and correspond to the well-known 'myombo' woodlands of east, central and southern Africa.

This excursion, and two trips near Yangambi, provided a unique opportunity for some of Africa's leading ecologists to see together a good range of vegetation types and to discuss them in the field, while travelling, and at the end of each day. This field-work provided an excellent basis for the more formal meetings at Yangambi. There was a considerable measure of agreement concerning the recognition in the field of the plant communities and how they are influenced by biotic, edaphic and climatic factors. It was encouraging to find that on many points workers had independently come to similar conclusions. The greatest divergence of opinion was in matters concerning nomenclature and the concept of the climatic climax. The informal discussions about the latter more academic point were particularly lively and valuable.

Matters of nomenclature were dealt with in the formal sessions at Yangambi. MM. Aubréville, Trochain and Monod each presented classifications of the main types of tropical African vegetation. These and other participants worked hard during the meeting to produce a classification of physiognomic types with parallel names and diagnoses in French and English. This agreed synthesis is to form a basis for a synopsis of tropical African vegetation, illustrated by profile diagrams and photographs, which, it is hoped, M. Aubréville will shortly prepare for publication.

Prof. Monod presented a remarkable account, intended for publication, of the chorological divisions, that is, the broad patterns of distribution not only of the vegetation and plant species but also of the animals.

The meeting reviewed the present state of vegetation-mapping in Africa south of the Sahara and proposed the creation of a permanent centre in Africa to which all new maps of interest to phytogeographers would be sent, and from which research workers could borrow maps. It also considered proposals for the preparation of a botanical atlas of Africa, including vegetation maps on a scale of 1 : 5,000,000, as well as maps showing the distribution of economic species and other subjects.

The Conseil Scientifique pour l'Afrique au Sud du Sahara, and in particular Prof. Lebrun, are to be congratulated on organizing such a useful meeting, and it is to be hoped that means will be found to implement many of its recommendations.

R. W. J. Keay

NINTH INTERNATIONAL CONGRESS OF APPLIED MECHANICS

THE ninth International Congress of Applied Mechanics was held at the Université Libre of Brussels during September 5–13. More than seven hundred members attended the Congress, and no less than five hundred communications were presented. The Congress was administered by the International Committee for Congresses of Mechanics, which is one of the organizations adhering to the International Union of Theoretical and Applied Mechanics. The president was Prof. F. van den Dungen and the secretary-general M. Jean Vandenkerckhove. A feature of the organization was the special provision which was made for young scientists, who were able to obtain cheap accommodation and meals in the Cité Universitaire, while a grant of 2,000 dollars was also available to help with their expenses of travelling to Brussels.

The main interest of the Congress naturally centred around the one-hour addresses. Mr. K. S. Davidson, of the Stevens Institute of Technology, Hoboken, N.J., gave a lecture on "Ships", in which hydrodynamics, boundary-layer theory and practical yachtsmanship were pleasantly combined. Much of the substance of this lecture is available in the Sir Geoffrey Taylor Memorial Volume entitled "Surveys in Mechanics" (Cambridge University Press, 1956).

Prof. R. Hill, of the University of Nottingham, gave a lecture on "New Horizons in the Mechanics of Solids". In this lecture he set up a theoretical framework sufficiently general to include problems of visco-elastic solids, including the theory of creep and work hardening.

Prof. P. Germain, of the University of Lille, lectured on "Some Recent Advances in Theoretical High Speed Aerodynamics". This was a general survey of problems of linearized supersonic theory treated by the method of the Laplace transform. Some extensions to second-order effects were also included in the lecture, which was remarkable for the speed with which it covered almost all recent developments in this subject.

Prof. H. Mettler, of the Technische Hochschule, Karlsruhe, spoke on "Forced Non-linear Vibrations of Elastic Bodies".

But perhaps the address which was most appreciated was that by Sir Geoffrey Taylor, which bore the title of "Steady Flow of Fluid entering a Region through Porous Boundaries", and which in fact dealt with the hydrodynamics of paper-making, and of painting with rollers and ordinary artists' brushes. In this extremely interesting address, Sir Geoffrey gave an account of the recent work which he has carried out to investigate the flow of the paper pulp over the rollers in paper-making machines. His investigations of roller painting and of brush painting consisted not only of simple theories embodying the main physical factors, but also of experiments which satisfactorily bore out the predictions of the theory and which were remarkable for the economy of material with which they were executed.

Apart from these general addresses, the work of the Congress was divided into two sections, the first dealing with fluid mechanics and containing some 258 papers, and the second with the mechanics of solids, containing 243 papers. In view of this great mass of material, it was necessary to limit the time available for the presentation of most papers to 15 minutes, although a certain number were given 30 minutes. The papers were grouped in such a way that only two papers were ever being read at the same time, namely, a 30-minute paper in Section I and a 15-minute paper in Section II, or vice versa.

The section on fluid mechanics included papers on aerodynamics in subsonic, transonic, supersonic and hypersonic conditions, on atmospheric pollution, boundary-layer theory, hydrodynamics of water-entry problems and surface waves, lubrication, cavitation, and seepage problems in the Nile valley. A particularly interesting demonstration was given by Prof. M. Reiner, of the Israel Institute of Technology, of his centripetal pump. This machine consists of two parallel plates ground accurately flat, of which one forms the stator and the other the rotor. A pressure hole is located at the centre of the stator and the rotor is rotated at a few thousand revolutions per minute. Initially, the pressure at the centre of the stator is reduced; but as the distance between the plates is progressively reduced to a few thousandths of an inch, a pressure of several feet of water is built up.

The section on the mechanics of solids included some papers on classical problems of vibrations, on the elastic theory of plates and shells, on buckling and post-buckling problems, and on a yielding sub-soil; but the emphasis seemed to be on plasticity, limit analysis, creep and visco-elasticity.

Mention must also be made of the social activities and of the financial support which the Congress received from Belgian banks and industries. Members of the Congress enjoyed the traditional Belgian hospitality at two receptions and a banquet. A reception was given at the University by the President, Vice-President and Rector of the Free University of Brussels and a reception at the Town Hall by M. L. Cooremans, mayor of Brussels. The banquet was held at the Hotel Metropole.

It is planned to hold the next International Congress of Applied Mechanics in 1960 in Italy.

THE NUCLEI OF ATMOSPHERIC CONDENSATION

ATMOSPHERIC aerosols cover a wide range of particle-size from about 10^{-7} cm. for the small ions to more than 10μ radius for the largest salt and dust particles, and a range of concentrations from less than $100/\text{cm.}^3$ over the oceans and in the upper air to, perhaps, $10^6/\text{cm.}^3$ in the polluted air of large cities. Being the products of natural and man-made combustion, of dust and spray raised from the Earth's surface, of chemical reactions taking place in the atmosphere, and perhaps even of matter entering the atmosphere from outer space, the particles will vary greatly in chemical composition and, because of coagulation, will often be of mixed constitution. The abundance, size, physical properties and nature of these particles are matters of particular interest to those working in the fields of cloud physics, atmospheric electricity, atmospheric pollution and atmospheric chemistry.

Since the pioneer work of Aitken seventy-five years ago, a great deal of effort has been devoted to measurement of the concentration, size, mobility and electric charge of the smaller particles with radius between 10^{-7} and 2×10^{-5} cm. But in recent years more attention has been given to the particles larger than 0·1μ in diameter—the so-called 'large' and 'giant' nuclei—since it is these which are mainly responsible for the formation of cloud droplets. The selective sampling of these larger particles has necessitated the development of new techniques for collection and measurement; but at these sizes it now becomes possible to use electron microscopy, electron diffraction and microchemical methods for identification.

These trends were reflected in the proceedings of the Second International Symposium on Condensation Nuclei, held in Basle and Locarno during October 1–4 and attended by scientists from ten countries.

After the delegates had been welcomed by Prof. F. Verzár on behalf of the organizing committee, the conference opened with a review by Dr. B. J. Mason (Imperial College, London) in which he summarized and assessed the present state of knowledge concerning the abundance, size distribution, physical properties, nature and origin of condensation nuclei, particularly of those which are likely to be involved in cloud formation.

An interesting paper by A. C. Chamberlain, W. J. Megaw and R. D. Wiffen (Harwell) described the consequences of the attachment of radioactive particles (particularly the decay products of radon and thoron) to condensation nuclei, the use of radioactive markers to study the behaviour of condensation nuclei, and the production of condensation nuclei by ionizing radiations. The diffusion constant of radium A and thorium B ions was found to be 0·054 cm.²/sec. when uncombined, and of order 10^{-5} cm.²/sec. when attached to condensation nuclei, this difference having an important effect on the site of deposition in the human respiratory system of inhaled radioactive matter. Unattached radioactive particles are largely deposited in the nose, trachea and bronchi, but the attached particles penetrate to the alveoli. The new radioactive method of determining the diffusion constant of nuclei gave results which differ from those obtained by the normal methods by a factor of about two—a discrepancy which has still to be resolved.

Reviewing the methods of measuring the concentration of Aitken nuclei, Prof. L. W. Pollak (Dublin) stressed the limitations of the Aitken pocket counter and of the Schulz counter and described the development, calibration and accuracy of the Nolan–Pollak photoelectric counter, which has proved a much more satisfactory instrument. There followed papers by various members of the Dublin school describing a nucleus counter with stereophotographic recording of the deposited droplets, the formation and decay of the fog in the photoelectric counter, and the results of some experiments carried out with Verzár's automatic photoelectric counter.

There were two other papers of particular interest from the instrumental point of view. Prof. A. Goetz (Pasadena) described an ingenious device for the separation and size classification of airborne particles greater than 0·2μ diameter. The particle-laden air is introduced into the space between a helical screw and an outer cylinder rotated at high speed. The particles are deposited on the surface of the helix under a centrifugal acceleration, the linear displacement being proportional to the ratio particle diameter/mass. Under these conditions, the particles move only slowly relative to the air and so are not subjected to large shearing forces.

Dr. J. Podzimek (Prague) described some preliminary experiments on the formation and growth of clouds produced in Findeisen's large expansion chamber (capacity 2 m.³) and, in particular, the effects of varying the initial temperature, expansion ratio and rate of expansion (that is, the rate of cooling of the air).

The role of condensation nuclei in atmospheric electricity, and in particular the effect of their concentration, charge and mobility on the conductivity of the air, was the subject of papers by H. Israël (Aachen), J. A. Chalmers (Durham) and Herpertz, Israel and Verzár.

Dr. C. Junge (Air Force Research Center, Cambridge, Mass.) described the results which have emerged from the chemical analysis of samples of rain-water collected once a month at some sixty stations spaced across the whole of the United States. Maps showing the geographical distribution of chlorides are very similar from month to month, with high concentrations near the coast, but dropping to a fairly constant value inland. This, together with the fact that the total number of giant salt particles occurring in unit vertical column of the atmosphere is much the same over both land and sea, suggests that the air undergoes strong vertical mixing when it passes over the continent, and also that the giant salt particles are not effectively removed from the atmosphere by rain. Junge estimates the mean half-life of the giant salt particles to be three to four days in the eastern part of the United States, where the average rainfall is 0·1 in./day, and six to seven days in the western part of the continent, where the average daily rainfall is only 0·05 in. The half-life of the smaller natural aerosols, measured by radioactive techniques, was estimated to be about twelve days. This all suggests that natural aerosols may be transported for great distances over the Earth before falling out or being washed out by precipitation.

During the second part of the conference, held in Locarno, Prof. Giuseppina Aliverti (Naples) reviewed recent researches on the condensation and ice-forming nuclei which are of particular interest in cloud physics.

Dr. B. J. Mason (London) reopened the old controversy as to whether salt particles produced by sea spray are the main source of condensation nuclei involved in cloud formation. His experiments show that air bubbles of diameter between ½ mm. and 2 mm., bursting in sea water, each produce about three hundred nuclei which, under the electron microscope, are mainly between 0·1μ and 0·5μ in diameter, the smallest containing only 10^{-15} gm. of sodium chloride. These results, together with measurements of the size distribution of salt nuclei collected over the oceans in areas of spray formation, indicate that the total concentrations of salt nuclei over the oceans in winds of up to 15 m./sec. probably do not exceed 100/cm.^{3}. The corresponding rate of production of salt nuclei at the sea surface is estimated to be 1,000/cm.^{2} sec. It was therefore inferred that sea-spray contributes perhaps only one-fifth of the nuclei involved in cloud formation, the majority being the products of combustion.

A paper by K. Isono (Tokyo) described how the residues of cloud droplets collected on the summit of a mountain 150 km. from the sea have been examined under the electron microscope and their nature determined by electron diffraction. Most of the nuclei are less than 1μ in diameter; about 30 per cent consisted of sodium chloride, 20 per cent of unidentified soluble particles, and 50 per cent of insoluble particles—probably combustion products.

H. Dessens (France) has established that giant hygroscopic nuclei ($r > 10\mu$) exist in concentrations of at least 100/m.^{3} in the equatorial forests of the Belgian Congo, while nuclei of radius less than $0 \cdot 4\mu$ are present in much higher concentrations. No sodium chloride crystals have been identified among the giant particles, the most important source probably being the savannah fires. M. Dessens also described some very interesting experiments in which he has been able to produce quite large cumulus clouds in an otherwise clear sky by the burning of vegetation.

Other aspects of the subject were represented by contributions from H. W. Georgii (Frankfurt) on the measurement of the turbulent diffusion of aerosols near the ground, and by F. Volz (Mainz) on the production of dusts and their spatial distribution in the atmosphere.

Although a good deal of the material presented was not entirely new, the conference produced much vigorous and good-humoured discussion and some clarification and agreement as to what are the important problems. These include the collection and identification of the large and giant nuclei over both land and sea at different levels in the atmosphere, and investigation of the processes by which they are produced and transported.

The organizing committee is to be congratulated on the excellence of the arrangements in ideal surroundings. The proceedings of the conference will be published in a special issue of *Geofisica Pura e Applicata*. It is expected that the next symposium will be held in Britain in 1958. B. J. MASON

WORLD TELECOMMUNICATION

THE major part of the inaugural address as president of the Institution of Electrical Engineers, delivered by Sir Gordon Radley, director general of the Post Office, on October 4, was devoted to a consideration of world telecommunication, a subject particularly topical in view of the recent opening to traffic of the first trans-Atlantic telephone cable. The practical realization of inter-continental multi-channel telephone communication by submarine cable is, in Sir Gordon's view, revolutionary in its possibilities, because the traffic capacities of such cables are likely to exceed the existing demand for telegraph and telephone facilities on their routes. It is important to appreciate that it is the advent of the submerged repeater or amplifier which has rendered long-distance submarine telephony practicable. The attenuation of the Newfoundland–Scotland section of the trans-Atlantic telephone cable at 164 kc./s. is approximately 1·6 db. per nautical mile, and an input power at the enormous level of 100 MW. would not be detectable by the most sensitive galvanometer at a distance greater than 150 miles. In the cable, repeaters are inserted every 38 miles, and the gain of each of these is 65 db., representing a power amplification greater than 10^6. On this basis multi-channel telephony is practicable on the longest submarine circuits.

The trans-Atlantic cable circuit utilizes, for the longest ocean link, separate cables for the two directions of transmission. The 'one-way' repeaters in these cables are accommodated in flexible housings only a little larger in diameter than the cable itself. These repeaters can be passed over the laying gear of the cable ship, and laying can be carried on continuously as with a conventional cable. The alternative arrangement of two-way transmission on a single cable requires a considerably greater space in the repeater housing to accommodate the additional filters and more complex circuits. The rigid housings for these repeaters require special handling in laying and considerably complicate that operation. The devising of means whereby the laying of such rigid repeaters could be carried out as part of a continuous cable-laying operation is, in fact, an immediate task of great importance.

Sir Gordon devoted considerable attention to the relative costs of single- and double-cable schemes, illustrating the matter by curves showing the estimated capital cost and annual cost per telephone circuit for cables 2,000 miles long, plotted to a base of total band-width transmitted in each direction. The cost per circuit is shown to decrease rapidly as the band-width or total capacity of the system is increased. It is thus economically advantageous to include in one cable, or pair of cables, all required facilities, telegraphy, telephony and—ultimately—television.

In regard to the economics of telephone-cable schemes on the main cable routes of the world, there appears to be a marked distinction between the North Atlantic route and all others. Sir Gordon remarked that the impetus to the growth of traffic between Western Europe and North America given by the 1956 telephone cable might well produce an early demand for a second cable of the greatest capacity technically possible. Eighty circuits in a single-cable system or two hundred in a twin-cable system was an objective only just beyond the limits at present imposed by repeater spacing and cable diameter, and either system, if reasonably loaded with traffic at the present call-rates, would be profitable.

On other world routes the economic prospects are less promising. Circuits to Australia and New Zealand, 12,000 miles long, might have a volume of traffic between 5 per cent and 10 per cent of the traffic with North America. It is clear that, for so great a distance with a small group of circuits, cable could not be competitive on cost with radio. On the other hand, experience of the propagation of high-frequency waves has shown that satisfactory radio communication cannot be maintained continuously over such difficult routes as the North Atlantic, or to the Antipodes.

It thus appears that the challenge to the communication engineer is that of providing submarine cable facilities on the main trunk routes of the world on a similar scale to that which has become established practice on land. This challenge is of very direct concern to British manufacturers, for Britain has a unique tradition of submarine cable manufacture and has an exceptionally large manufacturing capacity for this class of equipment.

In relation to inland telecommunication, Sir Gordon stated that "electronic techniques are likely to revolutionize the art of telephone switching within the foreseeable future". Fully electronic switching systems are being developed along two distinct lines, one in which gas diodes or other corresponding devices are used in a 'space multiplex' to connect speech paths, and the other in which time-division multiplex operation enables individual subscribers to communicate. The production cost of an electronic exchange is likely to be less than that of the corresponding mechanical equipment, and it is thought that maintenance costs should also be reduced.

A new facility is planned for the trunk telephone network of Great Britain in the form of subscriber-dialling of long-distance calls. To render this practicable, it is necessary to have a nation-wide number scheme, and the system is being planned on the basis of 20 million subscribers connected to 8,000 telephone exchanges.

In the trunk network, co-axial cables carrying 600 speech channels are in operation between the main centres of population, and similar plant modified to transmit a slightly wider band of frequencies is used for television. It is proposed, on these co-axial cable routes, to reduce the spacing between repeater stations to three miles, if sufficient traffic offers, as this would enable each tube of the cable to carry 1,000 telephone channels plus a 405-line television channel. The micro-wave radio relay system planned for Britain is capable of carrying 600 channels of telephony, or one television channel.

In his concluding remarks, Sir Gordon mentioned that he had not followed the example of his predecessors in office during the past few years as he had made no reference to the great need in Britain for more technologists, or to the means of training them. He had, however, described a few of the problems and projects which at present are challenging the ingenuity and energy of the telecommunication engineer, and he hoped that in so doing he might have kindled here and there a spark of interest and enthusiasm for work in a field of endeavour where much can be done to serve the nation, the Commonwealth, and the world at large.

J. GREIG

CITY AND GUILDS OF LONDON INSTITUTE

THE year 1955 was a memorable one for the City and Guilds of London Institute in that the entries for the Institute's examinations exceeded a hundred thousand for the first time. From 1878 until 1955 more than 1½ million people have entered for the Institute's examinations, and the fact that half a million of these have done so within the past six years emphasizes how great has been the expansion of technical education. During the year many new subjects have been introduced to meet new needs, and a large number of existing subjects have been carefully reviewed and where necessary the syllabuses have been modified.

The Institute regularly surveys its schemes not merely as separate subjects but also in their relationship to each other and in relation to their place in the national economy. As an example, some account is given in the annual report of those subjects which have a particular bearing on the proper use of the nation's fuel resources and the contribution which appropriate courses of study can make to industrial fuel efficiency.

The Associated Examining Board for the General Certificate of Education, for which the Institute has undertaken the administrative and financial responsibility in the initial years, has now been successfully launched. In the first examination, held in the summer of 1955, nearly five thousand papers were taken in more than seventy subjects at ordinary and advanced levels, and the entry figure has been more than doubled in the summer examination of 1956. Omissions in the list of subjects offered by the Board are continually being made good, and the new subjects recently approved include commercial subjects (including shorthand and typewriting) at ordinary level, music at ordinary level, and dress at ordinary and advanced levels.

The report also contains an account of the way the Institute has been re-organized to meet the challenge of changing times.

NITROGEN METABOLISM AS AFFECTED BY POTASSIUM DEFICIENCY

SOME new and interesting aspects of nitrogen metabolism in barley, especially as it is affected by potassium deficiency, have been investigated by R. G. Coleman and F. J. Richards (*Ann. Bot.*, N.S., 20, 79, 393; 1956). Barley was grown in water and sand culture, using a variety of nutrient solutions, the most important variable being potassium supply. It was observed that the diamine putrescine, which is not normally found in this plant in appreciable amounts, was present in potassium-deficient seedlings and that it accumulated during their growth. Its maximum accumulation coincided with the development of the severe symptoms associated with advanced deficiency. Putrescine occurs at an earlier stage in potassium-deficient plants, the nitrate and phosphate of which are supplied as ammonium salts, than in those to which the corresponding calcium salts are given. It is found less abundantly in the roots than in the tops. It is absent from protein hydrolysates.

These investigators have also shown that a leaf necrosis characteristic of potassium deficiency can be induced by feeding putrescine to barley having a high potassium status after prolonged feeding the appearance of such plants suggested severe potassium starvation. The putrescine is slowly utilized, and at the same time an unidentified substance is produced. It is stated that what seems to be the same substance appears in quantity in high-potassium red clover during the course of rapid utilization of administered putrescine. It also occurs naturally in potassium-deficient red clover. When potassium is supplied to potassium-deficient barley in which putrescine has accumulated, the amine soon disappears. Application of either rubidium or sodium also leads to a reduction in putrescine, though to a lesser extent, rubidium being the more effective element. Under conditions of extreme potassium-deficiency, wheat and red clover also accumulate putrescine. The free amino-acid composition of the wheat then bears a striking resemblance to that of deficient barley.

PHYSIOLOGY OF MUSCLE

THE Medical Department of the British Council has once more been able to persuade a group of active and distinguished scientists to leave their benches and spend time on summarizing and interpreting recent progress in a field of active research—this time, the physiology of voluntary muscle (*British Medical Bulletin*, 12, No. 3, 161 (1956). London: British Council. 15*s*. net). There are sixteen reviews in this symposium, and they succeed in giving a clear, connected and up-to-date summary of research in the physiology, biochemistry and biophysics of this type of muscle. The scientific editor is W. D. M. Paton, and the chairman of the planning committee is Sir Rudolph Peters, who contributes an introduction.

A. V. Hill contributes essays on thermodynamics and on the design of muscles. He mentions that an animal's muscles could be quickened about 20 per cent by raising its body temperature 2 deg. C., and he wonders whether, if this were achieved rapidly by diathermy, it would enable a good runner to do 100 yards in 8 seconds. He points out, though, that the margin of safety in mechanical strength of muscle systems is a small one and thinks that the experiment would be risky. There is an essay by A. F. Huxley, illustrated by photomicrographs, on the interpretation of muscle striations, based on work with modern techniques of light microscopy. This is followed by one on the 'ultra-structure' of muscle as revealed by the electron microscope and the X-ray camera (H. E. Huxley). It is possible by means of suitable salt solutions to extract the main proteins of muscle selectively, so that the residual structure can be viewed after successive removal of myosin and actin. The results suggest a delightfully simple picture of muscle as being made up of discontinuous, parallel filaments of myosin and of actin which seem to slide or 'crawl' past one another during contraction, perhaps because of the pull exerted by oblique cross-linkages between the molecules of the two proteins. Adenosine triphosphate can affect this interaction and may itself be broken down by myosin. The word 'crawl' would scarcely seem apt to R. G. Bannister, who contributes a section on muscle effort in running. In spite of the limits set by speed of muscle contraction or of oxygen supply, he believes that in a race, psychological factors—mental excitement and ability to ignore pain—"set the razor's edge between defeat and victory".

Mrs. D. M. Needham describes the biochemical reactions which provide energy for muscle contraction. In the past, glycogen and creatine phosphate have successively been displaced from the role of primary energy source in muscle. Whether adenosine triphosphate will suffer the same fate remains to be seen, though there are hints of this in the work of H. A. Krebs and his colleagues and of W. F. H. M. Mommaerts (see *Nature*, 174, 1081; 1954). At present, adenosine triphosphate seems to occupy the key position even after death, and E. C. Bate-Smith and J. R. Bendall show that the onset of rigor depends on the fall in the concentration, or in the turn-over rate, of this substance to a critical level. Other biochemical features of muscle are considered by K. Bailey and by S. V. Perry in their essays on the protein and enzyme systems of muscle.

The comparative physiology of muscle is discussed by C. F. A. Pantin and the methods of locomotion in fishes and four-footed animals by Sir James Gray. The role of the cell membrane is described by B. Katz, particularly the phenomenon of liberation of acetylcholine in quanta or 'pre-formed parcels' at the nerve–muscle junction. The only article of immediate clinical application is the one on familial periodic paralysis by B. McArdle, though Sir Rudolph Peters points out in his introduction that most of the academic research reviewed in the other essays is needed to provide a basis for complete understanding of this one disease.

Most of the reviews contain an up-to-date and fairly extensive bibliography, which greatly adds to their usefulness.

SENSITIVITY OF IMMATURE MOUSE SPERM TO THE MUTAGENIC EFFECTS OF X-RAYS

By Dr. A. J. BATEMAN*

Cytogenetics Department, Christie Hospital and Holt Radium Institute, Manchester

IN an earlier communication[1], I questioned the accepted view that the first three weeks mating of a male mouse irradiated with a dose in the neighbourhood of 500 r. represented *all* the post-meiotic stages of sperm at the time of irradiation[2,3]. My objection was based upon data being accumulated at the time and which can now be presented.

The mutagenic response was studied in terms of dominant lethals. Twelve days after their insemination, females were dissected and the numbers of corpora lutea, implantation sites and dead implants recorded. From this last category were excluded fœtuses which had made appreciable growth before death. In so far as they are genetic in origin, these would arise from gene mutation rather than chromosome breakage and loss, which is the source of the main type of dominant lethal mutation.

It is usual (for example, Russell *et al.*[3]) to estimate the proportion of dominant lethals from the corpora lutea not represented by live fœtuses. This will include all dominant lethals; but unfortunately it will also include all unfertilized eggs. There is likely to be a substantial and erratic proportion of unfertilized eggs even in the control series (matings of unirradiated males), which is therefore an important source of random error. But if the treatment affects the amount of sperm, its fertilizing capacity, or even its ability having effected fertilization to promote cleavage, there is the possibility of a systematic error.

---

* British Empire Cancer Campaign Fellow.

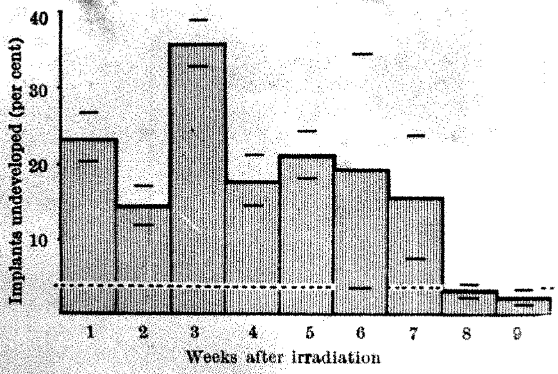

Fig. 1. Dominant lethal rates in successive weekly samples of sperm following the irradiation of male mice with 200 r. The broken line shows the control value: 3·78 per cent. The standard errors of the weekly means are indicated by the thin horizontal lines above and below

In the data here presented, only the proportion of implantations without signs of a fœtus is considered. While excluding in this way about half the true dominant lethals (those failing to be implanted) the above-listed sources of error are also excluded, and the control value is conveniently low and constant. There is one important unproved assumption: that the frequency of failed implantations is proportional to the *total* incidence of dominant lethals. There is some evidence that this is approximately true. Meanwhile, the convenience of the method is a good recommendation. The only improvement would be a method which was able to distinguish between unimplanted eggs due to dominant lethals and those due to other causes, which would probably necessitate the cytological examination of all the eggs at a critical stage after fertilization.

Both irradiated males and the females to which they were mated were F_1 hybrids between two large-bodied strains supplied by Dr. D. S. Falconer of Edinburgh. They are vigorous, mate readily and have high ovulation-rates. The modal number of corpora lutea is 14–15.

The males were given a testis dose of 200 r. They were then placed with four females each, which were renewed at weekly intervals for nine weeks.

Nine males were analysed in this way. There was no indication of heterogeneity between them. The mean weekly values for dominant lethals for all males are presented in Fig. 1, with the standard error based on variation between males.

The most important feature is the continuous incidence of dominant lethals over seven weeks, followed by a return to the control value by the eighth week. It is accepted that dominant lethals induced in pre-meiotic stages are not transmitted by the sperm. The detection of dominant lethals is therefore proof that these sperm were in a post-meiotic stage or, possibly, meiosis at the time of irradiation. It is concluded, therefore, that, contrary to many shorter estimates, spermiogenesis from spermatocyte to insemination in the mouse takes six weeks.

It may be objected that no allowance has been made for the possible storage of sperm after it has matured, thus producing an extension of the apparent length of the post-meiotic period. This assumption of sperm storage is common in the literature and is implied in all data in which matings are analysed according to mating sequence rather than the interval from irradiation[3,5]. There may well be stock differences in this matter; but my own material shows no evidence of the storage of sperm. On the contrary, it shows clear evidence that there is *no* storage.

Males given 500 r. become completely sterile after three weeks, whether or not they have been mated previously. Moreover, the raised mutation-rate detectable in the third week is also found to be independent of the previous mating history. This absence of storage is consistent with the anatomy of the genital system, which has no storage organ, the so-called 'vesiculæ seminales' being secretory organs containing material for the vaginal plug.

If spermiogenesis takes six weeks, it follows that the failure to obtain progeny from males over three weeks from irradiation with doses of the order of 500 r. must be due to the lethal effect of such doses on immature sperm, in much the same way that 30,000 r. kills immature *Drosophila* sperm[4].

Fig. 1 shows a marked peak in mutation for the third week. This confirms the observations of Auerbach and Slizynski[2] for translocations, and that of earlier workers[3,5] for dominant lethals, following higher doses. In the present data the mutation-rate in the third week is more than twice that in the second.

After this peak, however, the mutation-rate falls in the fourth and fifth weeks to a level indistinguishable from that of the two weeks before the peak. Evidently the mutagenic sensitivity of the earliest stages of spermiogenesis is no greater than that of mature sperm. It is only at a certain critical stage, 2–3 weeks from maturity (week 3 samples sperm utilized 14–21 days after irradiation), that hypersensitivity is encountered. This is in direct contrast to *Drosophila*, where the peak sensitivity is found in the most immature spermatids.

Pronounced oligospermy is encountered during weeks 6 and 7. This explains the high standard error for these weeks. Owing to this high error we can say nothing more definite regarding the mutation-rate at this stage than that it is not significantly different from that of the two preceding weeks. Owing to the oligospermy there is a high degree of pseudopregnancy (more than 50 per cent), and the fertile matings have implantation-rates of only 40 per cent. Indeed the paucity of sperm was so great that none was found in the uteri of females shortly after insemination, though similar samples during all the other weeks showed abundant sperm. This is independent evidence that weeks 6 and 7 are close to meiosis, irradiation of which has been shown by Auerbach[6] to lead to oligospermy in *Drosophila*.

A minor point is the barely significant reduction in mutation from the first week to the second. The difference is 8·9 ± 4·2 per cent. Such an effect has been frequently encountered in *Drosophila* in comparing the first and second days mating[4,7].

To return to the main features of Fig. 1, it would appear that the variation in mutagenic sensitivity during spermiogenesis is *not* the same in mouse and *Drosophila*. A possible objection is that our assumption of a constant ratio of pre-implantation to post-implantation losses due to dominant lethals is not a valid one. But one would have to invoke extreme variation in the ratio to transform a *fall* in the ratio of post-implantation lethals to total implants into a *rise* in the total frequency of dominant lethals.

Another possibility which must be considered is that the recovered mutation-rate is not the primary one. Thus in sperm more than three weeks to maturity there might be selective elimination of those carrying dominant lethals. This possibility needs to be investigated further.

It may be concluded that spermiogenesis in the mouse takes 6–7 weeks. This is the period during which dominant lethals can be detected following a testis dose of 200 r. Unlike *Drosophila*, the highest mutagenic sensitivity is not found in the most immature spermatids, but in the relatively late stage sampled in the third week from irradiation. Before and after this peak the sensitivity is almost constant, being about half that of the peak. The incidence of dominant lethals among implantations alone is 35 per cent at the peak sensitivity and averages 20 per cent over the rest of spermiogenesis. The control value is 4 per cent. Assuming all these failed implants to be genetic in origin, we obtain as an estimate of the 'doubling dose', 50 r. (for the less-sensitive stages), which is the same as that calculated by Russell[8] for mutation in spermatogonia, and given extra weight by being cited in the recent White Paper on radiation hazards to man[9].

The data will be presented more fully and discussed more intensively elsewhere.

A DISTURBING FACTOR IN VERY HIGH FREQUENCY COMMUNICATIONS VIA IONOSPHERIC FORWARD SCATTER

By D. A. CROW and F. A. KITCHEN

Royal Naval Scientific Service, London

AND

G. A. ISTED and G. MILLINGTON

Marconi Research Laboratories, Great Baddow, Essex

IT is now well known that it is possible to communicate over long distances at very high frequencies by forward scatter from ionospheric turbulence[1-3]. Since the latter part of 1955, an elusive but persistent trouble has been experienced on an experimental scatter communications link from Gibraltar to the United Kingdom, operating on 37·30 Mc./s. Difficulty was experienced when attempts were made to receive teleprinter signals at 50 bauds with frequency-shift keying. Initially, the difficulty was evidently largely due to keying equipment faults, and the whole effect seemed to be greatly enhanced when the frequency deviation was increased from 2000 c./s. to 4800 c./s. in January. The effect manifested itself as a lack of purity in the note of the heterodyned signal, combined with a beat tone of the same order as the frequency deviation, and resulted in complete inability to print teletype correctly. The fact that the effect often appeared and disappeared within a very few minutes, and frequently coincided with some alteration made to the transmitter, at first suggested equipment troubles. However, when these had been carefully eliminated, the effect remained.

At this stage, some long-delay multipath effects were suspected, and it was clearly desirable to pulse-

modulate the transmitter to determine their origin. Since this was not possible directly, an approach to pulse modulation was achieved by sending a sequence of teleprinter letter-shift signals, which consist of the start digit (20 ms space), followed by all mark including the stop digit (a total of 130 ms). By observing with a narrow-band receiver tuned to the space frequency, the effect of a pulse transmission was obtained with 20 ms pulses at 6⅔ pulses per sec. At once it was observed that discrete delayed signal components were present, at approximately 20 and 40 msec. delay relative to the direct forward scatter signal. Occasionally 60 and 80 msec. delay components were detected, and also possible traces of later components up to 130 msec. Figs. 1 and 2 show these effects as originally observed on a visual display of the receiver outputs. The outputs from both mark and space channels are shown, the upper trace being the mark signal. Fig. 2 illustrates a most interesting distinction between the direct forward-scatter component of the signal, which carries a Doppler amplitude modulation of variable pitch, and the delayed signal components accompanying it, which have no such modulation. This suggested that the two signal components were being supported by different propagation mechanisms.

In order to obtain greater time discrimination between the delay components, and to disprove a suggestion that round-the-world echoes were involved, arrangements were made to reduce the pulse of space-frequency signal to 10 ms, while increasing that of the mark-frequency signal to about 200 ms. The result is shown in Fig. 3, where the separation of the components at discrete intervals of approximately 20 msec. is clearly seen. Timing marks at 20 ms intervals are shown on the mark signal trace. The film speed is slower than on the previous photographs, and this record is of the rectified audio output of the receiver. Fig. 4 shows a series of high-speed amplitude recordings made of the 'space' channel signal. That received from the transmitting array is shown in (*a*) and that from the transmitting dipole in (*b*). Both records were made within a space of half an hour and they are typical of propagation conditions existing in the morning during March. In each of the records the position of the direct signal component has been marked with a distinctive dot. Time advances from right to left, second intervals being indicated by the commencement of each black bar under the record. A calibration of relative amplitudes is included in Fig. 4(*a*).

The discrete nature of delayed signal components is well illustrated in each record, but it should be noted that in the dipole transmissions the direct signal component often disappears into noise. Further typical results obtained when transmissions were made on a horizontal dipole, instead of the normal directive array, are shown in Fig. 5. The direct component of the received signal is again of relatively small amplitude, whereas that of the delayed component is somewhat greater than that normally experienced using the array. This indicates quite clearly that the dipole radiation to the *rear* of the direct path is responsible for the enhancement in the amplitude of the delayed signal components. The appearance of the gap on the mark trace at the instant of the delayed signal component, rather than at the instant of the direct component, is to be expected under these conditions.

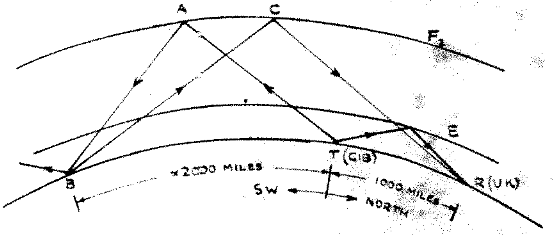

Fig. 6. Elevation of scatter signal paths

An earlier investigation⁴ had predicted that long-distance propagation of frequencies up to 50–55 Mc./s. due to normal *F*-region reflexion could be expected around mid-day in the months of seasonally high *F*-region ionization densities between the autumnal and vernal equinoxes, in years near the solar cycle maximum, thereby causing mutual interference between remotely situated, short-distance VHF services. Moreover, it has long been known that, under these conditions, scattered signals can be reflected back by the *F*2-region towards the transmitter⁵. At the time of the present observations, it was known from predicted data that the sunspot activity was rising very rapidly towards a high maximum, expected in 1957, and the other parameters were favourable to this mode of propagation coming into play for 37 Mc./s. at low latitudes, at least for certain daylight hours.

Consideration of available data on the *F*-region characteristics of the ionosphere led to the suggestion that, for several daylight hours, back radiation from the Gibraltar transmitting aerial was being propagated via this region to an area south of Gibraltar and

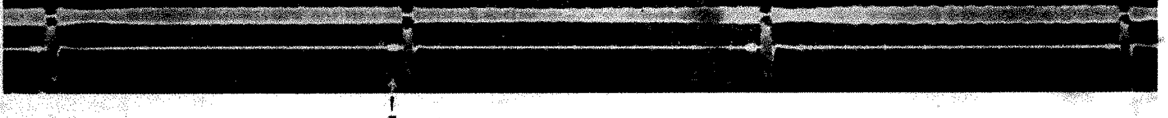

Fig. 5. 10-msec. pulse at *PRF* of 4 per sec., 15.35 hr., G.M.T., March 20, 1956. Reference dipole

Fig. 7. 50-baud letter shift, 20.25 hr., G.M.T., March 14, 1956. Directive array

scattered back by the ground or sea, the components of the scattered signal being re-transmitted via the *F*-region direct to the United Kingdom.

Such a process is illustrated in Fig. 6. The back radiation makes one hop via the *F*2 layer to an area approximately 2,000 statute miles to the rear of the Gibraltar aerial at *B*, where it is scattered back from the Earth's surface towards the United Kingdom by a single hop of 2,500 miles. The total difference of path-length between this path and the direct Gibraltar/United Kingdom path, allowing for the curvature of the Earth, the influence of the troposphere and the heights of the lower *E* and the *F*2 layers, is sufficient to give the observed delay of about 20 msec. on the earliest delayed component to arrive. An important point in this explanation is that the *F*2 reflexion point *A* for the backward hop was in a lower latitude than that of the corresponding point *C* for the forward hop. Thus, the higher ionization density at point *A* was able to support the higher-angle radiation required over the shorter path in the *F*2 region involved.

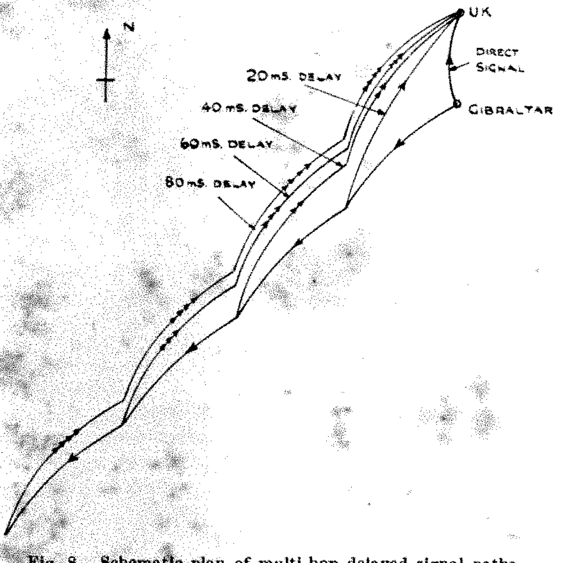

Fig. 8. Schematic plan of multi-hop delayed signal paths

It was at once confirmed that the effect was confined to daylight hours, showing a steady increase from its first occurrence at about 1000 G.M.T. to a maximum around 1600, and disappearing again quite sharply at about 1900. Fig. 7 shows the clear reception obtained later in the evening, which confirmed that the effect was not due to faulty transmitter keying. Afterwards, during the *S.I.D.* observed at 1620 G.M.T. on March 15, the delayed components disappeared completely for the duration of the disturbance, confirming that they are returned by *F*-region reflexion.

While the above explanation might serve for the first delay component, the later components could be accounted for by assuming that the back radiation from the transmitting aerial made two or more hops before being back-scattered and then returned to the receiver in the United Kingdom by similar hops (see Fig. 8). Each additional hop in this case would probably be of the order of 1,750 miles, to give a total additional delay of multiples of about 20 msec. Direction-finding measurements have shown that the delay components arrive from the south-west. This is in accord with measurements of the azimuthal radiation pattern of the Gibraltar transmitting aerial (Fig. 9), which shows that the back lobe of radiation is distorted to the westward by the upper flanking surface of the Rock. Radiation to the south-east is prevented by the upper mass of the Rock itself. The radiation in a south-westerly direction is sufficiently strong to support an 80 msec. delayed signal, as shown schematically in Fig. 8. It appears that such a delayed signal component could only be supported in this direction from Gibraltar, because of the distribution of *F*-region ionization density. In the absence of the Rock, the whole sector between the south-east and south-west directions from the transmitting site would be a potential source of delayed signal components. However, the discrete nature of the various delay components normally observed requires further investigation.

Support for this explanation of the delayed signal components experienced on 37 Mc./s. is available in that 45 Mc./s. television signals from the United Kingdom were being received concurrently in South Africa.

While it is clearly necessary to pursue this investigation further to confirm the identity of the mechanism by which these long-delayed multipath signals arise in VHF propagation in the lower latitudes, sufficient evidence is available to show that the

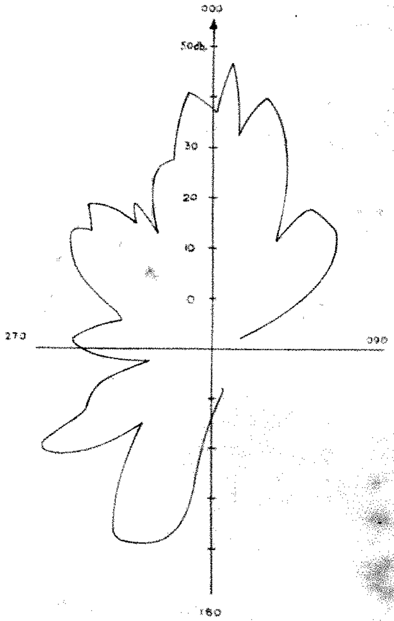

Fig. 9. Azimuthal radiation pattern of the Gibraltar transmitting aerial

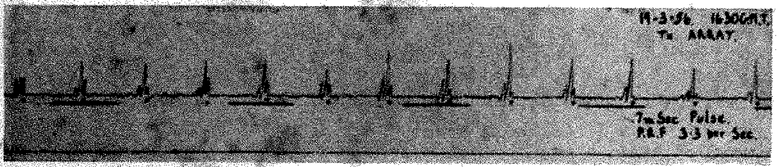

Fig. 10. High-speed amplitude recording during the late afternoon. Directive array

effect which these will have on operational automatic telegraphy circuits using VHF forward-scatter propagation in these areas may be disastrous. This is emphasized by Fig. 10, a typical record made of the array transmission in the late afternoon when the level of the direct signal component is low and that of the back-scattered component is normally high. Thus, from this record it can be seen that, in spite of the back-to-front protection of the array, the back-scattered component can be as much as 20 db. greater in amplitude than the direct forward-scatter component. This implies that, in order to achieve a safe 10db. signal/interference ratio, the present back-to-front ratio of the array must be improved by 30 db. While substantial improvement can doubtless be achieved by use of transmitting aerials of higher back-to-front ratio, allowance will have to be made for these effects and operational frequencies may have to be increased to values greater than 50 Mc./s. for periods near sunspot maximum[4]. The present effects are likely to continue for a few years, and may even be experienced under summer conditions on the present operating frequency.

The results described were obtained as part of a joint programme of research sponsored by the Admiralty and the Marconi Research Laboratories. Thanks are due to both these authorities for facilities granted in the conduct of the work, and for permission to publish this article.

DISTRIBUTION OF ANTHOCYANIN PIGMENTS IN POPPIES

By Dr. R. M. ACHESON
Department of Biochemistry
AND
Dr. JOHN L. HARPER and I. H. McNAUGHTON
Department of Agriculture, University of Oxford

IN the course of a comparative study of the biology of the cornfield poppies, *Papaver rhoeas*, *P. dubium*, *P. lecoqii*, *P. argemone* and *P. hybridum*, it was considered of interest to determine whether the slight differences in petal colour found in this group were due to qualitative differences in anthocyanin and, if so, whether the differences might be of taxonomic value.

On morphological grounds, *P. argemone* and *P. hybridum* constitute a distinct group possessing spines on the capsules and more dissected leaves than the smooth-capsuled species, *P. rhoeas*, *P. dubium* and *P. lecoqii*. The stamens of the former group possess laterally expanded, club-shaped filaments in contrast to the fine thread-like filaments of the latter species. Specimens labelled *P. hybridum* from several botanic gardens were markedly different from field collections of this species. Flowers were larger, were orange pink instead of the characteristic crimson of *P. hybridum*, and the degree of spine development on the capsule and the general growth habit were quite different. In the subsequent discussion this material is described as *Papaver* β pending further taxonomic investigation. Flower samples were collected from plants grown both in a greenhouse and in the field: the original seed samples were collected in the field or obtained from botanic gardens. Most of the species show a range of petal colour, and so, where possible, the extreme colour forms were examined for each species.

Anthocyanins were extracted by moistening the plant material with 0·1 per cent hydrochloric acid. Several species possess a characteristic black spot at the base of the petals and the pigments from the top and the base of the petals were therefore extracted separately.

Cyanidin and pelargonidin derivatives have previously been detected in the flowers of a number of *Papaver* species by colour and distribution reactions[1], and in the case of *P. rhoeas* two pigments were isolated[2]. Detailed studies have been made of the genetics of flower colour in *P. rhoeas*, especially in the cultivated Shirley poppy[3]. Chromatographic methods recently developed[4] permit an easier and more accurate characterization of the anthocyanins than the distribution reactions and have been applied to the flowers of the five *Papaver* species already listed above. Ascending chromatograms on Whatman No. 1 paper with *n*-butanol / acetic acid / water (40 : 10 : 50 by volume) at 22·5° C. gave better separation than when a descending solvent was used. The R_F values obtained were occasionally somewhat variable and so a minimum of four determinations was made on each flower extract. Synthetic fragasin (pelargonidin-3-galactoside, R_F 0·51), callistephin (pelargonidin-3-glucoside, R_F 0·55) or chrysanthemin (cyanidin-3-glucoside, R_F 0·35) were used as standards on every chromatogram, and the R_F values agreed with values already published[4] for the last two compounds (0·59 and 0·33).

Hydrolysis of the anthocyanins to the anthocyanidins and identification of the latter by colour reactions was undertaken and chromatographic comparisons were made with synthetic pelargonidin (R_F 0·70) and cyanidin (R_F 0·50) in the Forestal solvent[5]; Bate-Smith[5] gives R_F 0·68 and 0·50, respectively. Our results confirm and extend earlier less-detailed conclusions regarding both the anthocyanin content and distribution in *P. rhoeas* and *P argemone*, the only poppies of the *rhoeas* group which have been investigated from this aspect before.

Six distinct anthocyanins have been found in the poppies which we have examined, three cyanidin derivatives (*A*, *B* and *C*) and three pelargonidin derivatives (*A*, *B* and *C*). The species differ strikingly both in kind and distribution of these pigments (Fig. 1).

The petals of the morphologically similar species, *P. rhoeas*, *P. dubium* and *P. lecoqii*, contain only two anthocyanins, cyanidin *B* and pelargonidin *C*. The pelargonidin derivative is absent from the anthers where cyanidin *B* is present, and cyanidin *B* is abundant in the bases of the petals and absent from the tips (except in *P. rhoeas*, where it is present in lower concentration). No qualitative differences were detected between any of the colour variants of these species collected from the wild, but a specimen of the Shirley poppy lacked pelargonidin derivatives. A Shirley poppy examined by Robinson[1] lacked cyanidin derivatives. Scott-Moncrieff[3] has shown that the development of cyanidin and pelargonidin pigmentation in the Shirley poppy is genetically controlled and provides a biochemical interpretation of the results obtained by Newton and by Philp[3] in breeding experiments. Our results confirm those of Scott-Moncrieff in finding only one cyanidin derivative in *P. rhoeas*, whereas Schmidt and Huber[2] stated that a second cyanidin derivative was present.

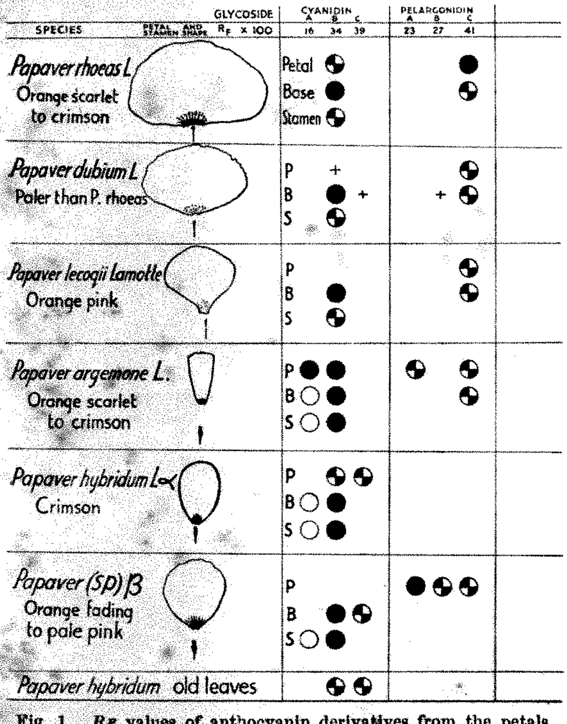

Fig. 1. R_F values of anthocyanin derivatives from the petals, stamens and leaves of *Papaver* spp. (*rhoeas* group). Typical petal and stamen shapes are illustrated, but the size of these organs and extent of the basal spot are very variable

●, Well-defined, relatively very intense spot; ◕, well-defined spot; ○, diffuse spot; +, found in only one specimen (see text)

Papaver argemone generally resembles *P. rhoeas* in the distribution of cyanidin *B* and pelargonidin *C*, although concentrations of cyanidin appear higher in the tips of the petals and the stamens. However, two additional anthocyanins are present in this species, a slow-moving cyanidin derivative (*A*) and a slow-moving pelargonidin derivative (*B*), both of which are in greatest concentration in the tips of the petals. No qualitative differences could be found between the pigments of orange and deep red forms of this species, but the amount of pelargonidin was less in the red form.

Papaver hybridum lacked all pelargonidin derivatives: cyanidin *A* was present in low concentrations in petal bases, where it was associated with the highest concentration of cyanidin *B*. In the tips of the petals a fast-moving anthocyanin (cyanidin *C*) was present. The botanic garden specimens β also contained all three cyanidin derivatives, but in addition three pelargonidin derivatives were present, the slow-moving pelargonidin *A* characteristic of *P. argemone*, the common pigment *C*, and in addition a further unknown anthocyanin, intermediate in R_F value between *A* and *C*, but giving a quite distinct spot. (A spot in this position was obtained from one sample of *P. dubium*, but was not found in any other samples.) Cyanidin *B* and *C* were also found in the old leaves of *Papaver* β. No other species developed pigments in the leaves.

No attempt has been made to identify the anthocyanins accurately, but it is worth noting that cyanidin *A* and cyanin (cyanidin-3 : 5-di-glucoside, R_F 0·16 [4]) and cyanidin *B* and chrysanthemin may be identical. Chromatographic identity of the pigments obtained from different species was shown by chromatography of mixed samples and the constituents on the same paper.

It is evident that the characteristic grouping of the anthocyanin pigments in different species supports groupings of the five species which might be made on morphological grounds. It can be seen that studies of the characteristics of petal pigments, even of species with rather similar coloration, may prove of taxonomic value; in this case the analysis of anthocyanins adds strong support to the original supposition that *P. hybridum* and the form β are distinct. In this connexion it may be noted that biochemical investigation has proved valuable in establishing relationships in the genus *Senecio*, where characteristic alkaloids of the necic acids are of taxonomic value[6].

Attempts are being made to synthesize hybrids of all the cited species, and, where possible, examination will be made of the anthocyanins present in F_1 and F_2 material.

The study of the biology of the poppies is being supported by a grant from the Nature Conservancy to the Department of Agriculture.

The Cones of the Grass Snake's Eye

In the course of an investigation of the photosensitive pigments of the grass snake retina, photomicrographs were taken of fresh flat retinal preparations. The retina was carefully removed from a newly killed animal and mounted in a drop of saline confined within a shallow wax ring on a coverglass with the outer retinal surface in contact with the glass. The whole was then inverted on to a slide[1] and examined under the microscope. In such a preparation the light passes across the retina in the same direction as it does in the living eye, that is, from the internal to the external limiting membrane, and then along the visual cells parallel to their long axes. What one looks at down the microscope is a cross-section of the visual cells.

All the visual cells of the retina of the grass snake (*Tropidonotus natrix natrix*) are cones (Fig. 1). These cones are a little unusual in the relative sizes of their inner and outer limbs. The outer limb of a cone is always more slender than the inner limb (unlike the rods, where the thicknesses of the two parts tend to be much more nearly equal) but the disproportion in the grass snake is markedly greater than is common.

When the fresh cones were viewed end on, as in the preparation described above, it was noticed that they appeared very bright when the microscope was focused on the outer limbs; but when the focus was moved down on to the inner limbs these appeared dark (Fig. 2). At the same time the cross-section of the cones increased very much. Photomicrographs were taken in monochromatic light, and the density of different parts of the preparation measured by means of a microdensitometer.

We found that at 578 and 640 mμ the intrinsic brightness of the light emerging from the tips of the outer limbs of the cones was greater than that transmitted through the plain glass of the slide and coverslip with the saline layer but no retinal tissue between. At shorter wave-lengths (436 and 546 mμ) there was some loss on passage through the retina and cone, but the tip of the outer limb still appeared intrinsically brighter than the surround.

This result can only mean that in some way light is condensed on passing through a cone on a path parallel to its axis or nearly so. The simplest way in which this could be accomplished would be if there were total internal reflexion within the cone, so that all the light which enters by the broad base of its inner limb on the internal limiting membrane is directed into the narrow tip of its outer limb. The idea of total internal reflexion of rays parallel to their axes within human cones has been put forward by Wright and Nelson[2] and elaborated by O'Brien[3] as a result of experiments with models. Such reflexion would prevent spreading of light after it is brought to a focus in the inner limb and might also explain the Stiles–Crawford effect. In addition, it would increase the absorption by pigment in the outer limbs of the cones. There are, of course, other possible explanations of the phenomenon described here, but in the absence from the grass-snake cone of any structure (except the inner limb as a whole) such as a paraboloid or oil droplet which might act as a condensing

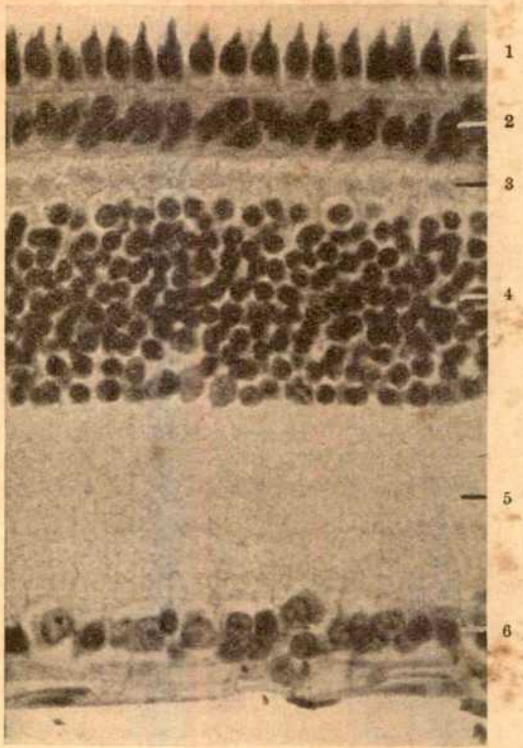

Fig. 1. Section through the pure-cone retina of the grass snake. (1) Cones; (2) outer nuclear layer; (3) outer fibre layer; (4) inner nuclear layer; (5) inner fibre layer; (6) ganglion cells. Kolmer's fixative; Mallory's phosphotungstic acid hæmatoxylin. × 440

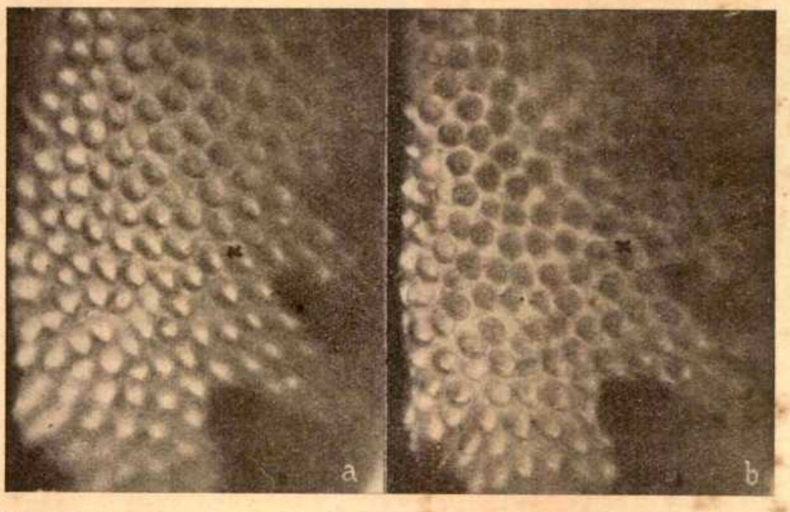

Fig. 2. Fresh snake cones. Two photomicrographs of the same field: (*a*) focused as far as possible on to the outer limbs; (*b*) at a lower focus. The cone marked × shows the bright outer limb in *a* and the larger, darker, inner limb in *b*. × 300. Photographed in 436 mμ light

lens, that of total internal reflexion seems to provide a reasonable preliminary hypothesis.

Survival of the Heart following Deep Hypothermia

DEEP hypothermia of warm-blooded animals favours the survival of their organs. For example, in the rat at normal body-temperature the heart ceases to beat several minutes after opening the chest, whereas in the rat cooled to 15° C. by the closed-vessel technique cardiac contractions can be seen approximately 1 hr. after respiratory arrest[1]. The intestine removed from a hypothermic dog contracts spontaneously when re-warmed and retains this property longer than an intestine isolated from a normothermic dog[2]. We have shown that the heart continues to beat for a much longer period after opening the thorax in rats which have been severely chilled and then re-warmed to normal body-temperature than in rats at the same temperature which had not been previously chilled[3].

The effect of profound hypothermia is shown equally well by survival of the heart after functional arrest. This is illustrated by the experiments to be described here.

When rats at normal body-temperature are killed by destroying the medulla and opening the chest, their hearts cease to beat after several minutes. If the bodies are then placed in the refrigerator at 6–9° C., cardiac contractions can be induced 6–12 hr. later in about half the animals by pouring Ringer's solution at 38–40° C. directly on to their hearts. Even after 48 hr. this technique sometimes elicits weak signs of activity around the orifices of the great veins.

Much more striking results are obtained if the rats are in a state of deep hypothermia when killed. Rats cooled by the closed-vessel technique[4] to body-temperatures between 13° and 16° C. were killed as described above and put with open thoraces in the refrigerator at 6–9° C. At this temperature the heart soon stops beating. Next day and on subsequent days the hearts are re-warmed by pouring over them Ringer's solution at 38–40° C. As a result, ventricular contractions are frequently seen several days after death, while rhythmic movements near the openings of the great veins have actually been seen when the corpses had been kept at 6–9° C. for as long as eighteen days.

Re-warming the heart for several moments daily by our method seems to prolong the functional survival which we have just described. We also noticed that this phenomenon is more regularly seen in exsanguinated hearts.

It is known that, in rats cooled to the point of freezing or even below, cardiac activity can be completely re-established approximately one hour after cessation of breathing and circulation[5]. Certain manifestations of myocardial activity can, as we have just seen, be observed many days after death provided that the rat was killed in deep hypothermia and the corpse stored at a low temperature.

The point is not, of course, that there is a genuine re-establishment of the functions of the heart, but only that there are a few signs of activity of the myocardium. Our results nevertheless indicate that deep hypothermia before death is favourable for survival of the myocardium. It might also be an advantage when transplanting or culturing organs and tissues from homœotherms to remove them from animals in deep hypothermia.

Effect of Surface-active Agents on the Living Cell

IT was observed some time ago[1] that treatment with surface-active agents influences the freshness and the keeping qualities of picked fruit and the development of cut flowers. When freshly picked fruit were sprayed with a dilute (0·01–0·1 per cent) solution of a surface-active substance the fruit kept about twice as long as the controls. It has also been demonstrated that similarly treated buds of freshly picked flowers can be forced to open prematurely.

Experiments have been carried out on the action of such compounds on living plants. Undiluted non-ionic surface-active agents were used, as earlier investigations seem to indicate that little effect can be obtained with dilute solutions.

Twelve bare twigs on a shrub of mock orange (*Philadelphus coronarius*) were painted with 'Tween 40' (polyoxyethylene sorbitan-mono-palmitate) at the beginning of August; on six of the twigs the treatment was repeated twice at intervals of one week. On the twigs which had been treated only once, the first green buds appeared six weeks later, 12–14 days before they did on any of the untreated branches. The twigs which had been treated three times remained bare throughout the summer.

On a red flowering rosebush three small rosebuds were painted with 'Triton *X* 100' (alkylated aryl poly-ether alcohol). Three days later the buds started to open, although they were only half the size of the buds which open under normal conditions. The flowers were distorted; their petals nearly colourless. This distortion was also observed when the experiment was repeated using other surface-active substances.

Four *Hibiscus* buds were painted with *G* 8916-*P* (polyoxyethylene-sorbitan esters of mixed fatty and resin acids). The buds started to open two days after the treatment, five days before the control buds which were at the same stage of development. In another experiment a branch of a *Hibiscus* shrub carrying several flower-buds was painted with 'Span 80' (sorbitan-mono-oleate). The effect of this substance could be observed for three weeks; all the flowers were slightly distorted.

Six *Hydrangea* twigs were painted with 'Triton *X* 100' at the end of winter and the treatment was repeated, after an interval of four weeks. On all the treated twigs axillary buds appeared first, 6–7 weeks before their appearance on the untreated branches.

Kurssanow[2] assumed that the enzymes in the plant cell synthesize or hydrolyse according to whether they are adsorbed or free. In recent years Veldstra[3] and Wain[4] have tried to correlate the structure and the surface-activity of different hormones with their physiological activity. We are attempting to show the action of surface-active compounds on animal cells. Such compounds of dissimilar constitution are very similar in action to plant-hormones; in further experiments on plants we hope to determine whether these compounds have themselves growth-regulating properties or whether they only stimulate the cells to produce growth-regulating substances.

Serum Protein Differences between Africans and Caucasians

THE use of starch gels as a supporting matrix for electrophoresis was found by Smithies[1] to result in much greater resolution of the serum globulins than can be achieved by the other media thus far employed. On the basis of differences in the behaviour of the α_2 globulins he was able to divide the Caucasians whom he studied into three qualitatively different groups and obtained evidence that these groups were the result of a Mendelian two-allele system showing no dominance, Types I and II*B* representing the two homozygotes and Type II*A* the heterozygote[2].

We recently have had an opportunity to examine a series of blood samples obtained from natives of Liberia and the Ivory Coast and find that the frequencies of the three types differ rather markedly in these samples from the frequencies thus far observed in Caucasians. The results are shown in Table 1. The values given for Caucasians were obtained by combining our unpublished data with those of Smithies[2], the two series being very similar. The difference between the two racial groups is highly significant. The frequency of the gene which when homozygous results in Type I can be calculated to be 0·42 in the Caucasians and 0·70 in the Africans. It thus appears that this trait may be of value in anthropological studies.

Table 1

Type	No. of individuals of each serum type			
	I	II*A*	II*B*	Total
Caucasians	16	54	33	103
Africans	69	60	13	142

$\chi^2 = 36{\cdot}77$. d.f. = 2

Although it has been possible to classify all the specimens thus far encountered with respect to the three Smithies types, there exist quantitative variations within the nominal types which raise the possibility that the genetic basis of these proteins may be more complex than originally postulated. However, the frequencies of the three types in the African sample agree unusually well with the assumption of equilibrium based on the genetic hypothesis of Smithies and Walker[2].

A second difference which has been discovered in the blood samples from Africa is the existence of qualitative variations in the protein fraction designated by Smithies[3] as $S\alpha_2$. In all these samples, this fraction migrates faster than the corresponding fraction of Caucasians, very nearly coinciding in hæmoglobin-complexed specimens with the slowest moving of the three bands which characterize II*A* individuals. This may lead to some difficulty in identifying the Smithies fractions. The significance of this additional variation, which may also be under genetic control, is being studied.

Reversible Degradation of Adenosine Triphosphate to Inosinic Acid during a Single Muscle Twitch

IN a muscle which performs mechanical work, adenosine triphosphate is degraded to inosinic acid. During aerobic rest, adenosine triphosphate is resynthesized from inosinic acid and creatine phosphate[1]. We have succeeded in demonstrating qualitatively that the same holds true in a single muscle twitch.

Isolated fibres from the frog's semi-tendinosus muscle were stretched perpendicular to a monochromatic ultra-violet beam. The light intensity was measured with a photomultiplier and the changes in photoelectric current recorded on a cathode-ray oscilloscope (Fig. 1: lower curves; a positive deflexion means an increase in light intensity). The tension of the fibre, as measured by a transducer, was recorded on the same oscilloscope screen (Fig. 1: upper curves), both beams being triggered by the stimulating pulse.

In the experiment illustrated in Fig. 1, there is a drop in light transmittance during the twitch at all wave-lengths from 546 to 240 mμ. In this experiment, scattered light has been excluded by the schlieren method. Any sudden rise in the scattering power of the muscle fibre would exert, in our condi-

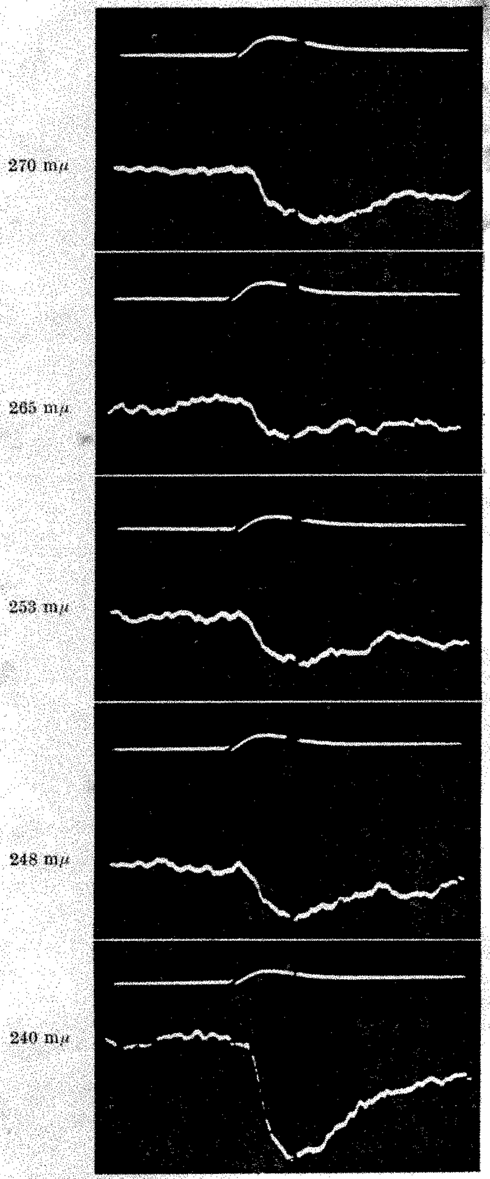

Fig. 1

tions, precisely the same unspecific effect on the total transmitted light: such a rise in scattering has been described for visible light[2].

At 265 mμ the drop in transmittance is markedly smaller than at 270 mμ or at 253 mμ, which means that an antagonistic effect, which cannot be other than a decrease in absorption, is superimposed on the scattering effect.

At 240 mμ the drop in transmittance is markedly larger, which shows that here an increase in absorption occurs.

The decrease in absorption at 265 mμ, the increase in absorption at 240 mμ, and no change at 248 mμ have been generally accepted since Kalckar's work[3] as a sign that adenine compounds are being deaminated to hypoxanthine compounds. The work reviewed above and the present material leave little doubt that what we have observed is in fact a reversible dephosphorylation–deamination of adenosine triphosphate during a single twitch.

We gratefully acknowledge the encouragement of Prof. A. von Muralt and Dr. S. Weidmann.

A Complement-fixation Reaction with *Haemobartonella muris* and *Eperythrozoon coccoides*

Hitherto no serological reactions were known in *Haemobartonella* and *Eperythrozoon* animal infections. In the present study, antigens of *H. muris* and *E. coccoides* have been prepared from heavily infected blood cells of splenectomized rats and mice respectively. The blood was hæmolysed by 0·01 *M* citrate buffer (*p*H 6), washed three times by centrifugation (10 min. at 4,500 r.p.m.) and resuspended in veronal-buffered saline[1]. In the case of *E. coccoides* a further antigen containing the free organisms could be prepared by spinning the plasma fraction at 6,000 *g* and using the sediment. The frozen antigens could be stored for a long period without appreciable loss of activity. Immune sera were obtained either from splenectomized rats and mice after recovery from infection or from normal animals 3–5 weeks after intraperitoneal inoculation of parasitized blood. Normal sera were obtained from animals of parasite-free breeds.

The micro-method of complement-fixation[2] was used throughout the experiments. This technique proved to be very advantageous, as often only small quantities of sera or antigens were available. A series of complement solutions, diluted by the factor 1·6, was always used. By this means the anticomplementary activities of antigens and sera could be taken into account. The titres were expressed in logarithms of fixed complement units, the 50 per cent hæmolysis being used as the end-point. Antigens prepared from parasite-free blood did not react. Normal sera showed a weak reaction with some antigen preparations only. The specificity of the reaction could thus be established. Two- and three-dimensional tests revealed a similar relationship between antigen, antibody, and complement as can be found in other complement-fixing systems.

The time-course of antibody formation against *H. muris* was followed by testing sera taken repeatedly from individual rats. In non-splenectomized *bartonella*-free rats antibodies arise about five days after infection. The climax is reached after 3–5 weeks

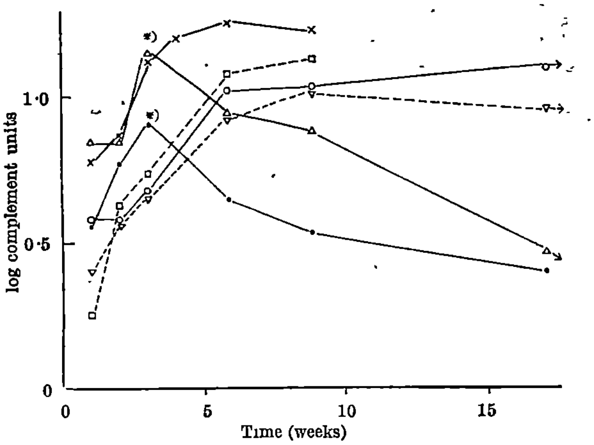

Fig. 1. Formation of antibodies after intraperitoneal infection with *H. muris* in non-splenectomized rats. 6 mgm. of neoarsphenamine at points marked *

(Fig. 1). Later on, the antibody-level remains constant for a long time. The latent infection of rats naturally infected with *H. muris* could thus be recognized by demonstrating complement-fixing antibodies in the sera. After treatment of the infection with neoarsphenamine the antibodies may gradually decrease (Fig. 1). The antibody-level of animals with latent infection diminishes after removal of the spleen, and the decrease is associated with an increase in the intensity of blood infection. The same occurs during relapses, when the parasite number increases (an example is shown in Fig. 2). The nature of this relationship between the undulations of the parasite number and the complement-fixing antibodies is uncertain. Neutralizing antibodies, which could conceivably account for the course of relapses, could not be demonstrated in any phase of the infection[3].

Different strains of *H. muris* showed no qualitative or quantitative antigenic differences in cross-fixation experiments. Furthermore, a unilateral cross-reaction between *H. muris* and *E. coccoides* could be demonstrated: *E. coccoides* immune sera reacted specifically with *H. muris* antigen; in the inverse case, however, no reaction occurred.

The complement-fixation reaction may be of practical use in the diagnosis of the carrier state in animal bartonelloses, as it has already proved to be in bovine anaplasmosis[4]. Moreover, it appears to offer a new method for the classification of animal bartonellas.

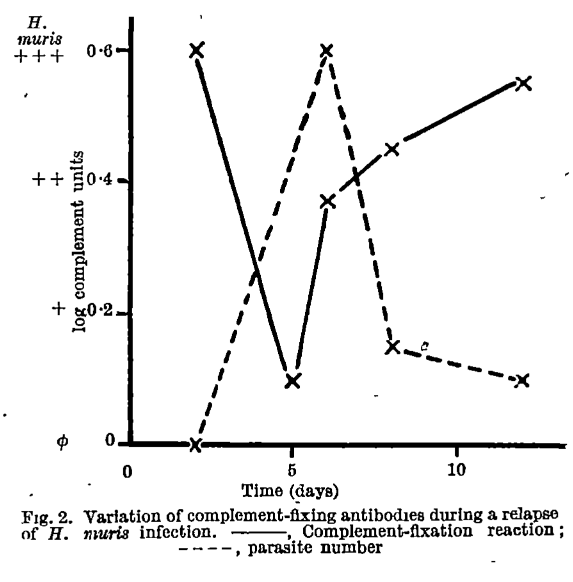

Fig. 2. Variation of complement-fixing antibodies during a relapse of *H. muris* infection. ———, Complement-fixation reaction; – – – –, parasite number

It should be mentioned that Marmorstone-Gottesman and Perla[5] as well as Lawkowicz[6] claimed to have demonstrated a complement-fixation reaction using cultured organisms from rat blood as antigens. The significance of these findings, however, is questionable, as the identity of the organisms with *H. muris* has not been proved.

Further results will be published in the *Zeitschrift für Tropenmedizin und Parasitologie*, and details of methods concerning the use and limitations of the micro-technique in the *Zeitschrift für Hygiene*.

Role of a D-glucosamine as Inhibitor of the Precipitation of Blood Group Substances by Anti-Type XIV Pneumococcus Serum

Beeson and Goebel[1] followed up earlier observations that human erythrocytes are agglutinated by Type XIV anti-pneumococcus horse serum[2] with the demonstration that blood group *A* substance obtained from commercial pepsin precipitated with the Type XIV antiserum. Subsequent studies have shown that blood group substances isolated from hog gastric mucin, human saliva and human stomachs by peptic digestion cross-react with anti-Type XIV serum[3]. Human blood group A, B or H substances isolated from ovarian cyst fluids by the phenol extraction method[4] do not precipitate to any appreciable extent in this system; but a strong cross-reactivity is developed after mild hydrolysis with acid[5] or by treatment with specific enzymes[6].

The detailed structure of the Type XIV pneumococcus polysaccharide has not yet been fully elucidated; but it is generally believed that the chemical basis for the cross-reactivity of the blood group substances with anti-Type XIV serum lies in the presence of galactose and *N*-acetyl-D-glucosamine in both the Type XIV polysaccharide and the blood group specific mucopolysaccharides[7]. Examination of the infra-red absorption spectrum of the Type XIV polysaccharide has indicated the presence of predominantly β-linkages[8]. Recently, Heidelberger[9] studied the precipitation of Type XIV antibody by a number of gums containing galactose, and concluded that multiple recurrences of non-reducing galactose end-groups suffice to produce cross-reactivity, but that gums with very few such end-groups which contain a number of 1,3- and/or 1,6- and/or 1,3,6-

Table 1. INHIBITION OF PRECIPITATION OF TYPE XIV PNEUMOCOCCUS ANTISERUM BY DEGRADED BLOOD GROUP SUBSTANCES

Inhibiting substance	Dilution of inhibiting substance			
	1:100	1 200	1 400	1 . 800
D-Galactose	1	2	3	3
L-Galactose	3	3	3	3
α-Methyl-D-galactopyranoside	1	2	3	3
β-Methyl-D-galactopyranoside	1	2	3	3
β-Methyl-D-galactofuranoside	3	3	3	3
Melibiose	1	2	3	3
Lactose	0	1	2	3
O-β-D-Galactosyl-(1→3)-*N*-acetyl glucosamine	1	2	2	3
O-β-D-Galactosyl-(1→4)-*N*-acetyl glucosamine	0	0	0	1
O-β-D-Galactosyl-(1→6)-*N*-acetyl glucosamine	1	2	2	3
Control (Type XIV antiserum + blood group substance)	3			

The inhibition tests were carried out using 0·1 ml. 1 1,000 conc. blood group substance, 0·1 ml. of inhibitor and 0 1 ml. horse anti-type XIV pneumococcus serum. Degree of inhibition read after standing at 1–2° for 1 hr. Increasing amount of precipitation recorded as 1, 2 or 3.

linked galactose residues precipitate the antiserum as readily.

The presence of units containing galactose linked to *N*-acetyl-D-glucosamine in human blood group substances is known from the isolation of O-β-D-galactopyranosyl-(1→4)-*N*-acetyl-D-glucosamine from meconium[10] and more recently from the isolation of (1→3)-, and (1→4)-O-(β-galactopyranosyl)-*N*-acetylglucosamine from *A*-substance of ovarian cyst origin[11]. Cross-reactivity of the blood group substances with antibody to Type XIV pneumococcal polysaccharide could be due to either of these disaccharide units or to some other disaccharide of galactose and *N*-acetylglucosamine which has not yet been identified in the group specific materials. The (1→3) and (1→4) compounds, together with O-β-D-galactopyranosyl-(1→6)-*N*-acetyl-D-glucosamine and a number of other sugars, have therefore been examined for their capacity to inhibit the precipitation of horse Type XIV pneumococcus antibody by preparations of human blood group substances which have been degraded by mild acid or enzyme treatment.

As shown in Table 1, D-galactose and all the methyl glycosides and disaccharides tested which contained D-galactopyranosyl units exhibited some capacity to inhibit precipitation. By far the most effective inhibitor, however, was O-β-D-galactopyranosyl-(1→4)-*N*-acetylglucosamine. The following sugars at a concentration of 1 per cent showed no detectable inhibition in this system: L-fucose, *N*-acetyl-D-glucosamine, α- and β-methyl-*N*-acetyl glucosaminides, *N*-acetyl-D-galactosamine, α-methyl *N*-acetylgalactosaminide, cellobiose and laminaribose. The increased efficiency of O-β-D-galactopyranosyl-(1→4)-*N*-acetyl-D-glucosamine over lactose (O-β-D-galactopyranosyl-(1→4)-glucose) as an inhibitor suggests that, although *N*-acetylglucosamine does not, by itself, prevent precipitation taking place, it plays an important part in the determinant specificity of the Type XIV antibody.

Inhibition reactions with simple substance have been widely used to study the relationship between chemical structure and serological specificity and, in general, the preferential inhibition of a precipitation reaction by a certain substance can be taken as an indication that a similar structure is present in the antigen under investigation[12]. The inference to be drawn from the results presented here, therefore, is that cross-reactivity of the blood group mucopolysaccharides with Type XIV pneumococcus antiserum is attributable, at least in part, to the presence in these substances of β-linked 1 : 4 galactopyranosyl-*N*-acetylglucosamine units.

We wish to thank Prof. R. Kuhn for specimens of (1→3)- and (1→6)-O-β-galactosyl-*N*-acetylglucosamine and Prof. P. Gyorgy for the corresponding O-β-galactosyl-(1→4)-*N*-acetylglucosamine. The investigation was supported by a grant from the Nuffield Trust.

Effect of Butyrate Administration on Blood Glucose in Sheep

THE concentration of glucose in the blood of ruminants has been found by earlier workers to change after the administration of butyrate. Blood glucose was depressed in goats after a transient rise[1], raised in adult sheep possibly by a sympatho-adrenal mechanism[2], and elevated in lambs with insulin-induced hypoglycæmia in a way that suggested glycogenesis[3]. Pharmacological reactions and great individual variation between sheep "made any statistical analysis difficult to interpret"[2].

During a study on gluconeogenesis in sheep[4], 500 ml. of a 10 per cent solution of sodium butyrate at *p*H 7·4 was infused during 50 min. into the jugular vein of Merino ewes. The pulse-rate rose to about 150 per min.; but distress or coma was avoided by the slow infusion. The initial blood glucose was in the normal range, was raised by glucose infusion, or was depressed by a fast of three days. Carotid and jugular blood samples were taken simultaneously before and after infusion and glucose determined[5]. The change in mean blood concentration (arterial plus venous divided by two) was plotted against the initial mean blood concentration (see Fig. 1).

When the blood glucose was initially around the normal average value[6] of 40 mgm./100 ml. it increased during butyrate infusion by 5–50 mgm./100 ml. in all but one case which decreased by 12 mgm./100 ml. When the ewes were fasted for three days, their blood glucose fell to 25–35 mgm./100 ml. and upon butyrate infusion it increased by 50–80 mgm./100 ml. When the blood glucose was high initially, it fell during butyrate infusion. The change in mean

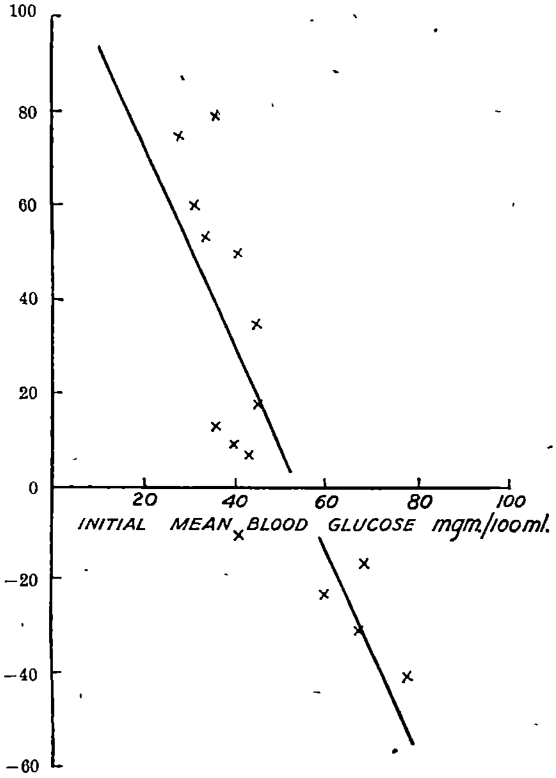

Fig. 1 Change in mean blood glucose in sheep 50 min. after infusion of 10 per cent sodium butyrate

blood glucose correlated with initial mean blood glucose ($r = 0{\cdot}848$) at a highly significant level ($p < 0{\cdot}001$) for fifteen observations.

These results indicate that sheep have a glucostatic mechanism which is facilitated by the administration of butyrate. Apparently gluconeogenesis from butyrate may occur in sheep; the conversion is inhibited by a plethora of glucose and is stimulated by a shortage.

Acquired Resistance to Chloroquine Diphosphate in *P. gallinaceum* in Chicks

Past experiments have shown that acquired resistance in *Plasmodia* to antimalarials can be developed easily and in a short time in certain groups of compounds. *Per contra,* such resistance to some other groups of anti-malarials can be built up either with difficulty or not at all. Proguanil and pyrimethamine belong to the former group, and it is noted that a *Plasmodium* made resistant to one becomes resistant also to the other[1-3].

Quinine, mepacrine, 4-aminoquinolines and 8-aminoquinolines belong to the latter group of compounds to which parasites do not seem to become resistant easily. For example, while Williamson *et al.*[4] failed to demonstrate any such resistance to quinine, Knoppers[5] had ultimately succeeded in developing only a two-fold resistance in *P. gallinaceum.* Again, only a slight degree of resistance could be built up in respect of pamaquine[6,7] and none at all to mepacrine[8,9] or the 4-aminoquinolines[10,11].

The present report records the findings of the development of at least a two-fold resistance to chloroquine diphosphate in *P. gallinaceum* in chicks. Although the exact mechanism of development of such acquired resistance is not fully known, it is noted from previous experience that whenever there had been a failure in the development of such resistance, either the initial dose was high and/or increase in doses was made very rapidly or abruptly. In view of this, during the present investigations, the initial dose administered was fairly low, the dosage schedules were increased cautiously, often the same dose was repeated over and over again, sometimes up to twelve times, during each passage, and lastly the strain was kept continuously exposed to the drug.

The procedure adopted for inoculation, drug administration, etc., was similar to that described earlier by Jaswant Singh, Basu and Ray[12]. Sub-passages were carried out on day 4 in respect of every batch after blood smears were taken for parasite count. Along with each experimental group, there was always an untreated group for comparison. The degree of parasitæmia in the experimental group was expressed as a percentage of that observed in the untreated group.

Before commencement of the studies, the minimum effective dose (the lowest dose which would reduce parasitæmia to approximately 25 per cent of the comparison group) of chloroquine diphosphate ('Avloclor', received through the courtesy of Imperial Chemical Industries, Ltd.) was first determined and it was observed to be 0·0615 mgm. per 50 gm. chick (equivalent to 1/26 of the M.E.D. of quinine). For development of acquired resistance, the initial dose selected was 0·05 mgm. per 50 gm., which allowed parasitic development to a reasonable degree (60–70 per cent as compared to the untreated group). The same dose was repeated three times in the succeeding passages before further increase in the schedule to 0·057 mgm. was made. Subsequent schedules were 0·0615, 0·066, 0·08, 0·088, 0·1, 0·114, and 0·123 mgm. per 50 gm. chick. The doses are equivalent to 1/26, 1/24, 1/20, 1/18, 1/16, 1/14 and 1/13 of the M.E.D. of quinine.

After nine months, during which period fifty-seven passages were made, a check test was initiated and repeated several times for confirmation. For this, both the parent strain and the sub-strain were exposed to the same dose of drugs in different batches of chicks. Side by side, untreated batches were kept for comparison. It was observed that under the dosage schedule of 0·0571 mgm., the degree of parasitæmia was somewhat similar (66 and 75 per cent) in respect of the two strains, but in groups treated with 0·0615 (M.E.D.) the parasitic densities were 28·2 and 62·5 per cent in respect of the parent strain and the sub-strain, respectively. In higher dosage schedules like 0·114 and 0·123 (1/14 and 1/13 the M.E.D. of quinine), the parasitic densities in respect of the parent strain were 0·018 and 0·009 per cent, respectively, against 33·3 and 27 per cent in respect of the sub-strain. In other words, the degree of parasitæmia (27 per cent) in the sub-strain under schedule 0·123 mgm. was about the same (28·2 per cent) as in the case of the parent strain under schedule 0·0615 mgm. At still higher dosage (0·133 mgm.), the infection rate was 6 per cent in respect of the sub-strain.

Therefore, while the M.E.D. for the parent strain was determined to be 0·0615 mgm., that for the sub-strain was 0·123 mgm. Thus the sub-strain could be considered to have developed a two-fold resistance. (Since submission of this communication, the sub-strain has now developed more than three-fold resistance to chloroquine-diphosphate.) Further observations are being continued, and details will be published elsewhere.

Enhancement of Activity in a Pacinian Corpuscle by Sympathomimetic Agents

It has been shown that the sensory input into the central nervous system can be modulated at the very origin of the nervous message—at the receptor[1]. For example, the response of a cutaneous touch receptor to a constant mechanical stimulus may be increased by excitation of the sympathetic nerve supply to the frog's skin. Only a few sympathetic impulses—in some cases only one—are required to modulate the activity of the receptor. The effect appears to be due to the release of an adrenaline-like substance by sympathetic fibres ending near the tactile receptor[1]. The present communication deals with the facilitatory action of sympathetic amines on an isolated mechano-receptive sense organ.

Pacinian corpuscles of the cat's mesentery were isolated, together with a length of sensory axon. For mechanical stimulation, the deflexions of a piezo-electric crystal produced by square voltage pulses of 0·1 msec. duration were transmitted to the corpuscle by a glass stylus[2]. The deflexions could be varied between 1 and 40μ, their magnitude being a known function of the voltage applied across the crystal. Threshold of the receptor could thus be expressed in terms of the voltage as well as in terms of the displacement of the crystal. The electric activity of the sense organ was led off at its afferent axon while physiological solutions containing test substances could be conveniently applied to the corpuscle. The application of adrenaline or noradrenaline caused a reversible lowering of the corpuscle's threshold for mechanical stimulation, which falls slowly to 90–70 per cent its original value in the course of 2–7 min. (Fig. 1). The effect was observed in 16 out of 19 cases tested and has a latent period of 1½–3 min. A latency of this order was to be expected in view of the very slow diffusion speeds of even relatively small ions across the layers of the corpuscle found by Gray and Sato[3]. Reversibility of the effect was obtained after repeated washing with physiological solution. Pairs or trains of sub-threshold mechanical stimuli which previously failed to excite the corpuscle to firing-level by temporal summation could be shown to add up to threshold during the period of increased excitability produced by the sympathetic agents. In about 20 per cent of the cases tested the addition of adrenaline or noradrenaline caused a reversible lowering of the adaptation-rate. Thus the corpuscle which ordinarily gave only a single impulse in response to a threshold stimulus discharged repetitively after the application of the sympathetic hormones. The appearance of iterated firing of impulses usually ran parallel with the period of highest excitability of the receptor (Fig. 1, *b* and *c*). Care was taken to maintain the stimuli continuously at threshold when the latter was decreasing under the influence of the amines. The repetitive firing appears to indicate, therefore, a genuine change in adaptation of the sense organ.

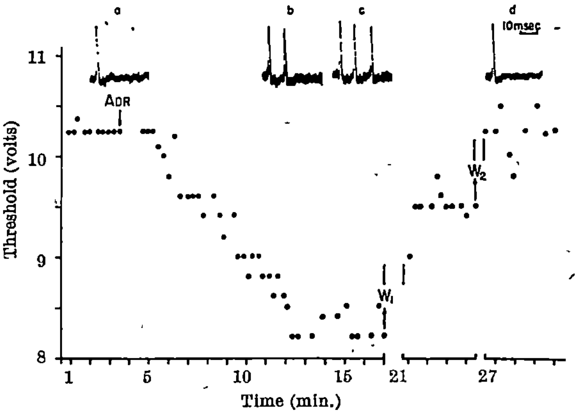

Fig. 1. Changes in excitability and adaptation of the corpuscle by adrenaline. 10 gm. in 10^6 ml. of adrenaline (*Adr*) are applied at arrow mark, causing lowering of threshold (expressed in volts applied across the piezo-electric crystal) and adaptation-rate (*b*, *c*). Reversibility is obtained after two periods of washing (*W*) with Ringer's solution. *a*, *b*, *c* and *d* are patterns of action potentials in response to threshold stimulation. The beginning of each pattern is placed in approximate accordance with the time along the abscissa

In a series of experiments a few corpuscles showed 'spontaneous' discharges at a steady rhythm in the absence of external stimulation. The application of adrenaline then caused an increase of 12–25 per cent of the impulse-rate.

Concentrations of 1–10 gm. in 10^6 ml. of adrenaline or noradrenaline were generally employed for the experiments. But clear effects could already be obtained with doses of 1 gm. in 10^7 ml.

The mechanism of action of the sympathetic hormones seems to be situated at the impulse generator of the corpuscle. 'Generator potentials' of the corpuscle's nerve ending were recorded with external leads at the emergence of the axon, while propagated action potentials were abolished by procaine[3] or by other blocking procedures. The latter will be described in another publication. The 'generator potentials' showed an increase in peak amplitude, an increase in rate of rise and, in some cases, a prolongation of its decay time, as a consequence of the addition of adrenaline. As the 'generator potentials' would normally present spontaneous fluctuations in shape in the course of the experiments, statistical analysis of the changes caused by the amines was necessary. The modifications in 'generator potential' mentioned above proved to be highly significant. The possibility of an antagonistic effect between adrenaline and procaine being responsible for these modifications may be discarded, since the same changes in 'generator potential' were found when other entirely different procedures for blocking of the action potential were used. A similarity between the facilitatory effects of adrenaline at diverse structures at which impulses are generated becomes apparent by comparing the increment of the 'end plate potential' of skeletal muscle[4], the alteration in the 'generator potential' of the heart's pacemaker[5,6] and the changes in 'generator potential' of a sensory nerve ending reported here.

This work was aided by a grant from the Rockefeller Foundation.

Binding of Histamine in Mammalian Tissues

MUCH of the histamine in mammalian tissues is contained in tissue mast cells[1]; but it is by no means certain how it is held at high concentration inside these cells. Evidence suggests that the mast cells do not produce the histamine but have a specific faculty of storing this compound. However, storage does not occur until metachromatically staining granules of heparin become visible in the cytoplasm of the cells. Experiments have been carried out, therefore, to study the affinity of histamine and heparin for one another.

When heparin (20 mgm.) and histamine acid phosphate (1 mgm.) are mixed in solution, and alcohol (70 per cent) or acetone is added, the precipitated heparin removes about 70 per cent of the histamine from the solution when the *p*H is around 5. The combination, however, is dependent upon *p*H, since at neutral or alkaline reaction much less histamine is removed by the heparin. Fig. 1 illustrates this point and compares the combination of heparin and histamine base (*B*, *p*H 9) with that of heparin and histamine acid phosphate or dihydrochloride. The precipitated heparin–histamine complex can be washed with alcohol or acetone without loss of histamine, but the complex is easily rendered soluble by water, saline or weak acid. If adenosine triphosphate (1 mgm.) is also present in the solution before precipitation, the uptake of histamine by heparin is increased to more than 90 per cent.

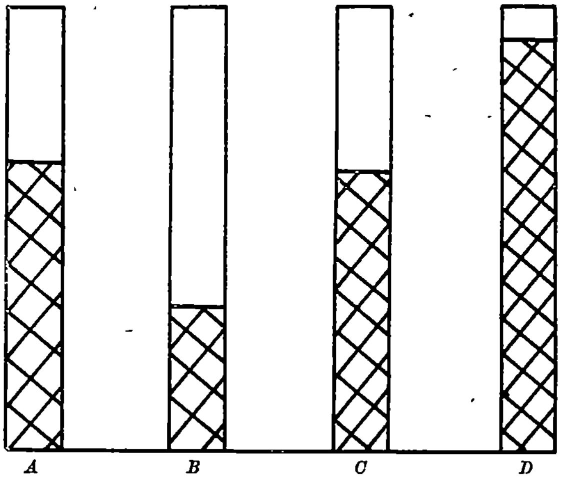

Fig. 1. Diagram to illustrate the distribution of histamine between the supernatant liquid (clear areas) and the precipitate of heparin (shaded areas). *A*, Histamine acid phosphate; *B*, histamine base; *C*, histamine dihydrochloride; *D*, histamine acid phosphate with adenosine triphosphate. All columns represent the means of ten experiments

The staining properties (for example, with toluidine blue) and chromatographic behaviour of the complex resemble those of the natural mast cell granules isolated from mouse connective tissue[2]. Further, the morphological characters of the precipitated complex approximate to those of the living granules.

The formation of the complex is fairly specific for histamine, since adrenaline, noradrenaline and 5-hydroxytryptamine are not removed under similar conditions. Certain basic amino-acids such as arginine, lysine or ornithine combine with heparin when alcohol is added[3]; and it is of interest to find that these amino-acids are bases of sufficient strength to displace histamine from its attachment to the acidic residue of heparin in the tissues by some kind of cation exchange[4].

Thus the base histamine and the acid heparin can form a complex *in vitro*. The proportions of the two substances present in the complex, namely, one part of histamine to twenty parts of heparin, are similar to those found in extracts of tissues which are rich in mast cells[5]. So far it has not been possible to release the histamine from the synthetic histamine heparinate without solution of the heparin.

Enzyme-Substrate Complex Formation : a First Stage in Ribonuclease Activity

THE exact intermediate steps in the breakdown caused by ribonuclease enzymic activity awaits clarification in spite of the many methods currently used in the measurement of ribonuclease activity.

The method presented here was found very useful for demonstrating the stepwise ribonuclease enzymic specificity. The technique depends on the fact that basic dyes which normally polymerize in aqueous

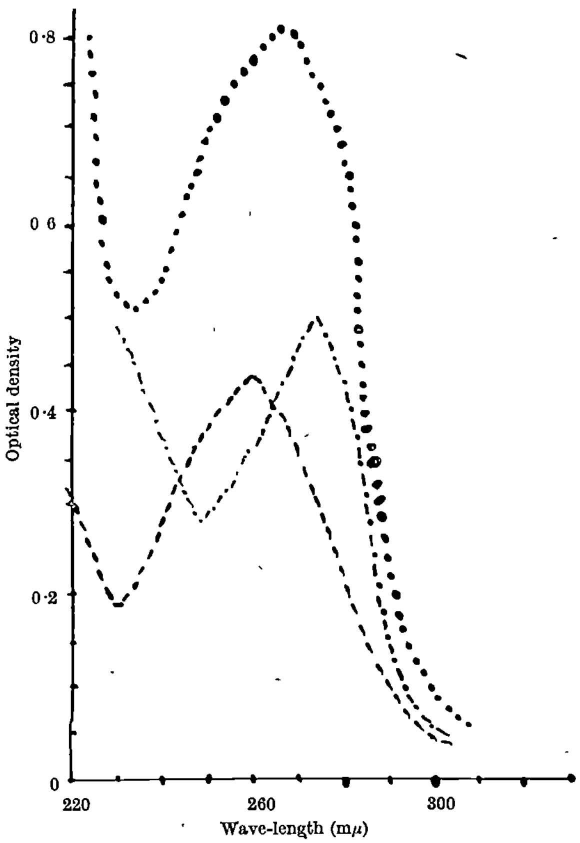

Fig. 1. Absorption curves of the elute: —.—, enzyme (ribonuclease); — — — —, substrate (ribonucleic acid); ...., enzyme-substrate complex (ribonuclease–ribonucleic acid) from the electrogram after ionophoretic separation

solution are depolymerized by nucleic acid, resulting in complex formation. Ionophoretic mobility of the dye–nucleic acid complex resulting is altered as enzymic activity progresses, thus giving a quantitative estimation for the action of ribonuclease on ribonucleic acid.

Using this procedure, an enzyme-substrate complex has been demonstrated using ribonuclease–ribonucleic acid (enzyme-substrate), desoxyribonuclease–desoxyribonucleic acid (enzyme-substrate), desoxyribonuclease–ribonucleic acid (enzyme-competing substrate) and ribonuclease–desoxyribonucleic acid (enzyme-competing substrate).

The materials employed include: (1) yeast ribonucleic acid, prepared and reported by Hakim[1,2]; (2) crystalline ribonuclease (Armour), triply recrystallized by the Kunitz procedure[3]; (3) desoxyribonuclease (Schwartz), recrystallized three times by the Kunitz procedure[4]; (4) sodium desoxyribonucleate, prepared by the method of Kay, Simmons and Dounce[5]; (5) methyl green solution, 0·4 per cent, after exhaustive extraction with chloroform to remove contaminating crystal violet, found by ionophoresis to be present in the commercial sample; (6) methylene blue.

Paper ionophoresis was carried out in type *LKB* 3276 paper ionophoresis equipment, using 40 × 10 mm. Schleicher and Schuell No. 2043 *B* filter paper, and a barbiturate buffer, *p*H 8·5, ionic strength 0·05.

Ribonucleic acid in 15 μl. volumes (1 per cent solution, w/v) was applied about 150 mm. from each end of the ionically equilibrated strips of filter paper, ribonuclease (or desoxyribonuclease) was applied on top of the nucleic acid spot in equal volumes (0·02 per cent solution, w/v). Finally, methyl green (or methylene blue) solution was applied in 5 μml. volumes (0·4 per cent solution, w/v). Four hours after the final application, a potential of 300 volts and 0·5 m.amp. was applied for 24 hr., after which the papers were dried. The location of the dye was noted, marked with a pencil, and the papers were stained with bromphenol blue to locate the position of the proteins. Experiments were run in triplicate on three parallel strips of filter paper. After ionophoresis and drying of the three ionograms, one strip was stained with bromphenol blue. In all cases, the enzyme-substrate complex was located at the line of application, while the different enzymes showed their own characteristic ionophoretic mobilities. Elution was accomplished in phosphate buffer *p*H 5·64, ionic strength 0·05, and activities of the eluates determined. Ribonuclease activity was measured by following the optical density of methylene blue (0·20 mgm./ml.) and ribonucleic acid (5 mgm./ml.), at 5500 A., as a function of time, following the addition of the eluate[6]. Desoxyribonuclease activity was measured by the Kunitz method[4].

Figs. 1 and 2 show the ultra-violet spectrophotometric spectra of the eluted enzyme (ribonuclease, or desoxyribonuclease), enzyme-substrate complex (ribo-

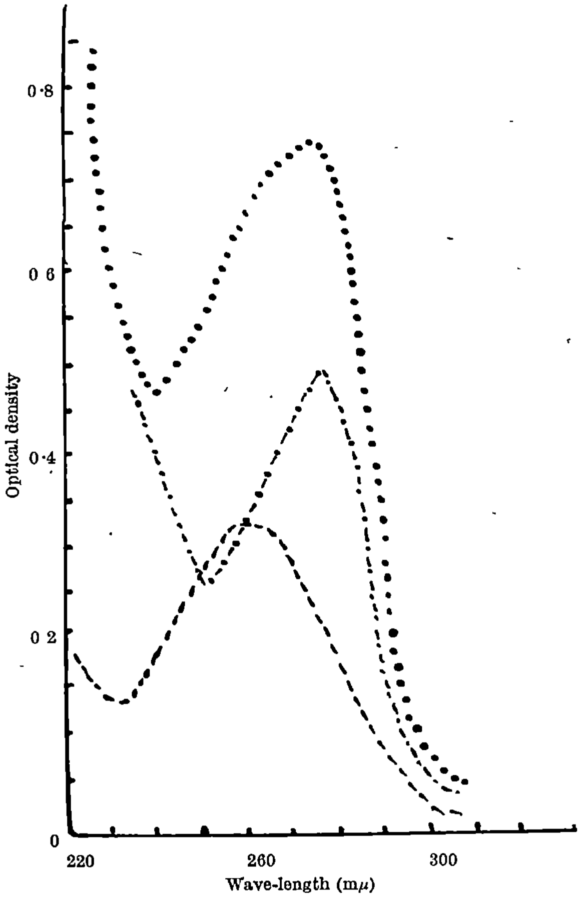

Fig. 2. Absorption curves of the elute: — —, enzyme (desoxyribonuclease); — — — —, substrate (desoxyribonucleic acid); ...., enzyme–competitive substrate (desoxyribonuclease–ribonucleic acid) from the electrogram after ionophoretic separation

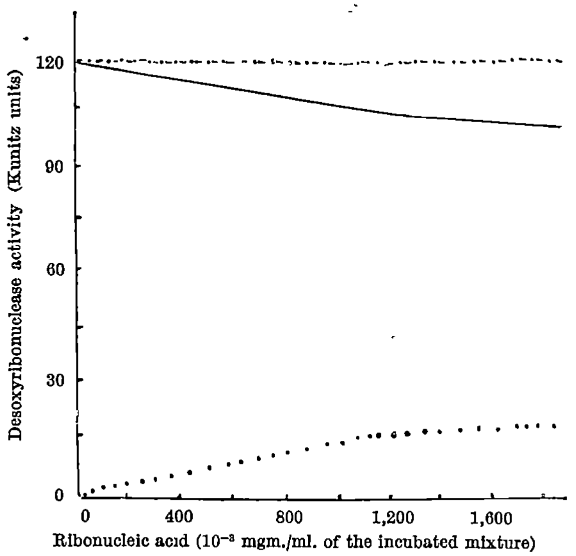

Fig. 3. Desoxyribonuclease inhibition by ribonucleic acid: — —, enzyme (desoxyribonuclease) added; ———, enzyme (desoxyribonuclease) found; ......, per cent inhibition

nuclease–ribonucleic acid, or desoxyribonuclease-desoxyribonucleic acid), enzyme-competitive substrate (desoxyribonuclease–ribonucleic acid), and substrate (ribonucleic, or desoxyribonucleic acid).

Figs. 3 and 4 show the results of experiments on paper ionophoresis, where fixed amounts of ribonuclease were incubated with increasing amounts of desoxyribonucleic acid on ionically equilibrated filter paper at room temperature. Ribonuclease activity then was titrated against yeast ribonucleic acid. In all cases the enzymic activity was found in the mobile fraction and not in the enzyme-competitive substrate complex, which remained at the point of application after ionophoresis. Similarly, fixed amounts of desoxyribonuclease were incubated with increasing amounts of ribonucleic acid and desoxyribonuclease activity was titrated against desoxyribonucleic acid (Fig. 3).

The competitive action between desoxyribonucleic acid and ribonucleic acid for ribonuclease has been demonstrated. The competition is due to the formation of complexes composed of the enzyme with either of the two acids.

Distribution in the Soft Tissue of the Rat of Radioactive Fluoride administered as Sodium Fluoride

Because the analysis of soft tissue for fluoride is difficult, little has been published on the distribution of fluoride in tissues other than bone, dentine and enamel. Data of this nature are of interest in view of the widespread use of fluorides in drinking water as a caries-preventive measure. Such data also may be useful in assessing the fluoride exposures of livestock pastured near certain industrial plants.

Preliminary experiments in which rats were given radiofluorine, reported here, afford additional insight into a number of aspects of fluoride metabolism. Radioactive fluoride was prepared by proton bombardment, in the small cyclotron of the University of Rochester Physics Department, of frozen samples of water enriched in oxygen-18. Following a 4–6 hr. bombardment, the ice now containing radioactive fluoride was melted, transferred to a 5-ml. volumetric flask containing aqueous sodium fluoride, and the solution brought to volume with distilled water; the final fluoride concentration was 1 p.p.m. Three different solutions were prepared; a different solution was used in each of the three distribution experiments (Table 1). Since samples from three different bombardments were employed, the data have been adjusted to the same activity, namely, 1,416, 200 counts per minute per microgram of fluoride, to facilitate comparison. The decay curve was determined for each sample. The half-life closely approximated 115 min.; in no instance was contaminant radioactivity detected.

At various intervals after administering the radioactive fluoride, the rats were killed by ether anæsthesia. The organs were removed in their entirety, with considerable care taken to minimize contamination by extraneous blood. The tissues were weighed, placed in beakers containing 20 per cent sodium hydroxide and digested on a hot plate as rapidly as possible. The digests were transferred to suitable volumetric flasks, diluted to volume, and 1-ml. aliquots counted by a surface-counting technique.

The experimental design was as follows.

Rat I: Four ml. of sodium fluoride solution containing 1 p.p.m. fluoride were administered by

stomach tube to an adult, female, albino rat; the animal was killed after 30 min. This procedure should give preliminary data on the soft-tissue distribution of fluoride as normally consumed per os.

Rat II: One ml. of the fluoride solution was injected into the femoral vein of an adult, female, albino rat; the animal was killed after 10 min.

Rat III: One ml. was given intravenously to an adult, female, albino rat which was killed 90 min. afterwards.

Results are given in Table 1. In the time available, total digestion of the carcass and skeleton was not accomplished; this accounts in great part for the low total recoveries obtained. The best recovery was obtained following oral administration; in this experiment more than half the administered dose was found in the stomach and small intestine, both easily digested organs. However, the relative distribution of fluoride can be compared in a number of the soft tissues.

The thyroid, kidneys, and adrenal glands contain the highest concentrations of fluoride following oral administration or 10 min. after intravenous administration. 90 min. after receiving fluoride by vein the kidneys and adrenals still contain the highest concentrations with somewhat less fluoride in the thyroid gland. By this time the parotid glands and spleen show increased fluoride concentration. The uptake of fluoride by the thyroid is in agreement with earlier work from this laboratory in which tissues were analysed chemically[1], but differs from the data of Wallace-Durbin, who found no accumulation of fluorine-18 by the rat thyroid[2]. The increased concentration in the parotid glands after 90 min. is in agreement with the results of Wallace-Durbin[2], Wills[3], and Volker, Sognnaes and Bibby[4], and is consistent with the view that these glands are sites of excretion of fluoride. The principal route of excretion of fluoride is via the kidney into the urine. Given intravenously, the fluoride concentrations were greatest in this organ; in the oral experiment it was the second highest. The intestinal secretion of fluoride[1,5] is revealed by the significant concentrations of fluoride in the small intestine following intravenous administration.

The sharp decrease in tissue fluoride concentrations from the tenth to the ninetieth minute after intravenous administration reflects the rapid removal of fluoride from the tissues and circulating blood. These results confirm the findings of Wallace-Durbin[2] and Parkinson *et al.*[5]. Normal human adults have excreted approximately one-third of an oral dose of fluoride in about 3 hr.[6].

We are indebted to Drs. J. A. Bruner and D. A. Bromley, and to Messrs. M. Awshalom and R. A. Campbell for these proton bombardments.

Occurrence of 'Lumps' of Coagulated Material in the Bladders of Adrenalectomized Guinea Pigs

During the past five years, seventy-six male guinea pigs from four different colonies have successfully undergone bilateral adrenalectomy. Of these, twenty-two have afterwards developed 'lumps' in their bladders. These animals appeared healthy until a few hours before death. The 'lumps', composed of a firm yellow cheese-like material and weighing 9–800 mgm., were circular with a diameter varying from approximately 0·25 to 1·0 cm. and they had frequently a small projection which might block the urethra. The bladder did not always contain urine, and the ureters were never dilated.

This phenomenon has never been seen in female guinea pigs nor in more than two thousand male guinea pigs killed or dying from other causes. It has only been observed in male animals which have been completely adrenalectomized for periods of four days to one year and either maintained on cortisone or deoxycorticosterone acetate or untreated apart from glucose–saline to drink. The lumps did not develop until both adrenal glands had been removed. There was no seasonal incidence.

Histological examination of sections (stained with hæmatoxylin and eosin) of the kidneys of four such animals was carried out. The kidneys of one appeared to be normal; but in the other three there was hyperæmia of the medulla, and also of the cortex in one animal. Two animals showed some cloudy swelling of the tubules, and in one there were zones of polymorph infiltration in the medulla. All the glomeruli appeared normal. The ureters, bladder and seminal vesicles were also sectioned, but no abnormality was seen. Urine samples were tested for albumen with salicylsulphonic acid. A positive result was sometimes obtained with urine from both normal and adrenalectomized animals; but there was no evidence of increased albuminuria or polyuria in adrenalectomized guinea pigs.

It seemed most probable that the coagulated secretion of seminal vesicles was the main constituent of the 'lumps'. Smears made of seminal vesicle secretion and those taken from the 'lumps' had a similar microscopic appearance and showed varying-sized rosettes of amorphous material. The similarity was even more striking when the smears were made from secretion which was first coagulated by immersing the whole vesicle in hot water. No spermatozoa have ever been seen in smears from either the secretions or the 'lumps'.

In the guinea pig, a greater amount of fluid is contributed to the semen by the seminal vesicles than by the rest of the accessory glands together[1]. Mann[1] has shown that the seminal vesicle secretion contains appreciable amounts of citric acid of the order of 200 mgm./100 ml.

In the present study, citric acid was determined by the method of McArdle[2] in the seminal vesicle secretion and in 24-hr. samples of urine collected from normal and adrenalectomized animals with and without 'lumps', in the 'lumps' themselves and in the urine recovered from the bladders of adrenalectomized animals at autopsy.

The results of citric acid analyses are summarized in Table 1.

As can be seen, the concentration of citric acid in the 'lumps' and in the seminal vesicle secretion was nearly the same, suggesting that the lumps were made up of coagulated vesicular secretion. It is of interest that the citric acid content of 24-hr. urine samples was higher in cortisone-treated or untreated adrenalectomized guinea pigs than in normal unoperated animals. The urine in the bladder of one adrenalectomized guinea pig not included in the series of figures given contained 737 mgm. citric acid/100 ml. urine. The urine was cloudy while in the bladder, and as soon as it was aspirated into the glass syringe it formed a solid mass.

Table 1. CITRIC ACID IN THE SEMINAL VESICLE SECRETION, URINE AND 'LUMPS' REMOVED FROM THE BLADDERS OF MALE GUINEA PIGS

Guinea pig	No. of animals used in the determinations	Material	Citric acid (± standard error) (mgm./100 ml.)
Normal	4	Vesicular secretion	174·0 ± 29·4
Adrenalectomized	12	Vesicular secretion	195·5 ± 16·3
Adrenalectomized	8	'Lumps'	192·0 ± 34·8
Adrenalectomized, with 'lumps'	7	Urine in the bladder at autopsy	66·8 ± 10·5
Adrenalectomized, without 'lumps'	4	Urine in the bladder at autopsy	94·1 ± 33·0
Normal	5	24-hr. urine sample	5·3 ± 0·6
Adrenalectomized, maintained on cortisone	4	24-hr. urine sample	28·8 ± 9·3
Adrenalectomized, no treatment for 6–24 days	9	24-hr. urine sample	41·5 ± 14·5

The actual cause of death was not evident. It seems unlikely that renal failure was the cause, since the onset of the terminal condition was very rapid; albuminuria was not gross, anuria did not develop, and the bladder was not always obstructed or distended.

It is well known that in some species, notably rodents, semen coagulates after ejaculation; in the guinea pig, coagulation normally occurs after mating so that a vaginal plug is formed. The tentative suggestion is made that in the adrenalectomized guinea pig, whether treated or untreated, the normal process of ejaculation and coagulation is disturbed and that coagulation takes place in the bladder; the 'lump' thus formed can no longer be ejaculated.

We are grateful to Dr. T. Mann for helpful discussion. The cortisone used in the maintenance of the adrenalectomized animals was a gift from the Medical Research Council.

Communal Oviposition in *Simulium damnosum* Theobald (Diptera, Simuliidae)

Simulium damnosum is the main vector of human onchocerciasis over a large part of tropical Africa. Although a considerable amount of work has been done on the habits of this insect—as summarized by Freeman and de Meillon[1]—there are many points in its biology which are still obscure, one of the most important of these being the normal method and site of oviposition. The only published description of the egg-laying habits of this species is that of Wanson and Henrard[2], who recorded thirty-five egg batches on specially attractive breeding sites mainly in the form of floating and vertical artificial frameworks of *Pennisetum* stems. Eighteen of these batches were deposited on the floating stems, thirteen on the vertical stems and four on artificial accumulations of stones. Ovipositing females did not penetrate the water but were observed to lay their eggs at or just above water-level; the egg batches consisted of 200–250 eggs. There is no record of the time of day on which oviposition was observed.

Since these observations were made, very little additional information on *Simulium damnosum* has appeared; but several illuminating observations have been made on species of *Simulium* in other countries which reveal a wide range of ovipositing behaviour both with regard to method and time. For example, Dalmat's observations on the blackflies of Guatemala[3], particularly those incriminated as vectors of onchocerciasis, showed that *S. ochraceum* oviposits by hovering above the less-turbulent parts of the stream and dropping relatively few eggs in any one place on the floating emergent vegetation. In the case of *S. metallicum* two methods of oviposition were observed; in a rapid current the female approaches the appropriate leaf at the surface of the water and deposits an egg without apparently landing. It then hovers above the leaf and returns to the same spot to deposit the second egg. In slow-moving streams the fly will actually land on the leaf, and several females —up to thirty—have been seen ovipositing on a single leaf. *S. callidum* was seen to oviposit only on sharply inclined surfaces of rock where the current was not very strong. The female hovers and then lands only long enough to deposit one egg, flying away to repeat the performance on another suitable surface. The time of oviposition of these three species was observed to be mainly between noon and 2 p.m. for *S. ochraceum*; between 5 and 6 p.m. (or occasionally as early as 3 p.m.) with *S. metallicum* and usually between 3.30 and 5.30 p.m. in *S. callidum*.

A further variation in ovipositing behaviour is shown by some North American species. *Simulium venustum*, for example, exhibits communal oviposition[4] while with *S. arcticum* it is considered that oviposition generally takes place on the surface of the river water, eggs being laid singly and sinking to the bottom[5].

In view of the wide potential range of behaviour likely to be encountered and of the paucity of observations on such an important species as *S. damnosum*, it was felt that a strenuous effort should be made to investigate this aspect of behaviour. The Liberian Institute provided unusual opportunities for this kind of work, as breeding of *S. damnosum* was found to occur regularly in parts of a comparatively small stream only 12 miles from the Institute. Repeated observations over several months, however, failed to reveal any sign of ovipositing females or of egg batches, even during periods of dense breeding. Finally, in March of this year *Simulium* eggs were found on several broad leaves of bushes dipping into the stream, bushes which had recently been cut down along the stream edge. The eggs were laid in large irregular masses, sometimes distinct, sometimes contiguous. As the eggs were piled in several layers it was difficult to assess their density or number; but a rough estimate showed that two to three thousand eggs per square centimetre was not unusual. On one particular leaf with a continuous egg mass about 30 sq. cm. it was estimated that there must have been at least 50,000 eggs. Provided the leaf surface was kept moist with spray it was found that the egg masses would extend two or three inches above the actual water surface. As larvæ hatching from these eggs could not be kept alive longer than a few days it was not possible to attribute them definitely to *S. damnosum*, as other species, particularly *S. cervicornutum* and *S. unicornutum*, were also present in this stream and on the trailing leaves.

In the following weeks many similar sites were examined, and further batches of eggs were seen twice on trailing leaves and twice on rattan strands dipping into the water. On the assumption that these egg masses were very likely those of *S. damnosum* it was already fairly clearly indicated that such masses could only have been produced by a large number of females, very likely ovipositing at one time. As observations carried out throughout the greater part of the day had failed to reveal any sign of ovipositing females, it also seemed increasingly likely that egg-laying would be restricted to the late afternoon or evening. The opportunity for confirming this point had to await a suitable combination of circumstances, the right time and the right place.

In the month of August, during a period of dense breeding of *S. damnosum*, one particular series of artificial sites in the form of leafy twigs dipping into the stream proved to be an unusually attractive ovipositing site in that fresh batches of eggs were recorded, not spasmodically but on several consecutive days. A careful watch was therefore kept on this spot during the hour before dusk. No fly activity was evident until dusk, when at about 1850 G.M.T. (sunset 1852 G.M.T.) a dense swarm of black flies was seen just above the surface of the water at the point where the tips of the leaves dipped into the stream. The swarm quickly settled on the trailing leaves and mass oviposition started immediately. On one leaf the swarm of flies, now obviously *S. damnosum*, settled at the tip trailing downstream and moved steadily from apex to base. As the mass of flies moved from the narrow tip to the broader part of the leaf they formed a solid line extending from one side to the other. As the line advanced steadily towards the base of the leaf the surface of the leaf behind them was left covered with a carpet of glistening white eggs (which turned brown during the course of the following few hours). As the flies moved upwards the entire leaf surface was covered with the white egg mass. Similar activity was also taking place on the two or three adjacent leaves of this twig, but not on any of the other eight similar twigs trailing in the stream at this point. By the time maximum ovipositing activity had been reached the waning light was making visibility difficult, and it is doubtful if the ovipositing swarm would ever have been spotted if attention had not been concentrated on this one suspected site.

When the peak of activity was already past, specimen tubes slipped quickly over two of the leaf tips secured 48 and 50 *damnosum* females respectively. As many flies escaped and as many others had already left the leaf it is fairly certain that two or three hundred females must have taken part in the pre-oviposition swarm and in the communal ovipositing itself. As a single female may lay several hundred eggs (200–250 according to Wanson and Henrard[2], or even up to 500[6]) it is now possible to understand how the previous estimate of anything up to 50,000 eggs on one leaf is not unreasonable.

This communal oviposition of *S. damnosum* appears to resemble in many respects that described for *S. venustum* (Hocking and Pickering, *loc. cit.*), in which the authors say that "egg-laying females were so numerous that they were lined up closely side by side while others crawled over them seeking a place". As far as *S. damnosum* itself is concerned this communal oviposition is evidently the regular method of ovipositing on this type of site, a leaf or branch trailing in the stream. On the other occasions when eggs have been found on such sites, whether natural or artificial, they have been in the form of large masses, undoubtedly the product of many females and in all those cases the appearance and dimensions of the eggs agreed with those of eggs actually laid by observed *S. damnosum* females. The dimension of the *damnosum* eggs—as judged by a random sampl of 20—were as follows:

	Length	Greatest breadth
Range	203–245 microns	126–140 microns
Mean	222μ	134μ

The observations of Dalmat quoted above to the effect that one species of *Simulium* may vary its ovipositing habits according to site and conditions, combined with the rather different behaviour of *damnosum* originally recorded by Wanson and Henrard[2], make it inadvisable to conclude that this communal ovipositing of *S. damnosum* is an unvarying feature of the species. As such ideal sites in the form of leafy twigs trailing in the turbulent part of the stream are rather unusual, other sites must be used as well in order to account for the almost continuous production of *S. damnosum* larvæ in this stream over long periods. Further observations are being made to investigate this point.

Effect of Changes in Humidity on the Toxicity and Distribution of Insecticides sorbed by some Dried Soils

Recently it has been noticed during field trials in mosquito control that there is an apparent correlation between relative humidity and the insecticidal effectiveness of deposits in houses made of mud walls and thatched roofs. Bordas and Navarro[1] in Mexico found a steady increase in toxicity of dieldrin deposits as the relative humidity increased throughout the season. Burnett[2] in Taveta, Kenya, found that seasonal variations in rainfall, presumably accompanied by variations in humidity, were associated with corresponding changes in the mortalities of mosquitoes exposed to dieldrin deposits.

Relative humidity could presumably exert its influence either upon the insect itself after the nsecticide has been picked up or it could modify he availability of the insecticide in the deposit, and these two aspects have now been examined in laboratory experiments.

We have not been able to find any effect of changes n relative humidity upon the kills of mosquitoes which were kept at humidities ranging from 20 to 5 per cent after topical application of DDT, gamma-BHC, dieldrin or 'Diazinon', or after exposure to eposits of wettable powders of DDT, gamma-BHC r dieldrin. Therefore it seems most likely that any nfluence of relative humidity is upon the availability f the insecticide to the insect.

It has been shown previously[3,4] that the air-dried oils which are frequently used for house construction n the tropics can rapidly adsorb insecticides applied s surface deposits of wettable powders. This process esults in a marked decrease in contact action of DDT and dieldrin because there are no longer any particles of insecticide lying on the surface of the house walls. We noticed in this work[3] that relative humidity had an influence upon the rates at which DDT and gamma-BHC thus disappeared; increasing the humidity reduced the rate of loss. It is therefore possible that the behaviour of deposits observed in field trials could be due to variations in the availability of insecticides on and in mud walls and this has been more fully investigated.

Table 1. The Effect of Changes in Relative Humidity upon the Toxicity of Dieldrin-treated Mud Blocks to *Aedes aegypti* Females

Relative humidity conditions	Percentage kill 24 hr. after exposure of . . . min.

It was confirmed that deposits of DDT, gamma-BHC and dieldrin on blocks of Uganda soil are sorbed at rates which decrease as the humidity increases. This was also observed on nine other soils of varying composition and origin. However, dieldrin, which was the insecticide of major interest with field experiments, even at a dosage of 100 mgm. per sq. ft. and at 90 per cent relative humidity, still disappeared from the surface of Uganda mud blocks in about five days, and so for interpretation of the field results it is of more importance to know what happens after sorption is completed. Table 1 shows the results of biological tests with mud blocks sprayed twenty-one days previously with a suspension of dieldrin crystals in the size range 0–10 microns at a dosage of 100 mgm. per sq. ft. and kept for 24 hr. at two different humidities before the exposure of mosquitoes. The positions of the blocks were reversed for a further 24 hr. and re-tested.

It can be seen that the insecticidal activity increases with humidity from 40 to 90 per cent and this difference in activity is almost completely reversible in 24 hr. Similar results were obtained for contact action of DDT and both contact and fumigant action of gamma-BHC. The kills therefore follow closely any changes in humidity and the biological effectiveness of the treated blocks can be rapidly raised or lowered. Because of this close correspondence it seemed unlikely that there could be any marked changes in distribution of insecticide as postulated by Bordas and Navarro[1], who suggested that the insecticide migrated back to the surface under conditions of high humidity. This was borne out by chemical determination of the distributions of the insecticides in the blocks kept at different humidities. These showed that the rate of diffusion of the insecticides into the blocks after sorption was complete actually increased with humidity and this naturally resulted in a decreased concentration of insecticide near the surface of the blocks on which the insects rested. Table 2 gives some results obtained with dieldrin-treated blocks kept at different humidities after spraying.

In the field, therefore, long periods of high humidity would be expected to give a progressive decrease in the concentration of insecticides near the surface of the walls whereas lower humidities would tend to keep the concentration static. At any given time and

Table 2. AVERAGE PERCENTAGE RECOVERIES OF DIELDRIN FROM SUCCESSIVE LAYERS OF UGANDA MUD BLOCKS

Relative humidity (per cent)	Layer No	Weight of layer (gm.)	Time after spraying		
			1 hr.	4 days	13 days
10	1	0·25	92	69	52
	2	4·0	8	31	48
	3	4·0	0	0	0
	4	4·0	—	—	0

	3	4·0	0	27	20
	4	4·0	—	20	15
	5	4·0	—	—	12
	6	4·0	—	—	10
	7	8·0	—	—	14

concentration, however, an increase in humidity would give higher kills, and a decrease lower kills. The enhanced kill at high humidities can more than compensate for decreases in concentration so that kills would remain high even during extended periods of high humidity.

We explain these results on the basis of competition between the water and the insecticides. Water appears to be adsorbed preferentially to the insecticide and the increased amounts which are present in soils at high humidities have two effects. The initial disappearance of the insecticide from solid particles lying on the surface is retarded because water molecules already occupy a large proportion of the 'active' surface of the soil and cannot be displaced. Once the insecticide is adsorbed, however, the same preferential adsorption of water results in an increased mobility of the insecticide molecules and therefore an enhanced rate of diffusion farther into the soil or, alternatively, an enhanced rate of diffusion on to and into an insect resting on the soil.

The laboratory findings therefore provide an explanation for the results obtained in the field by Burnett and by Bordas and Navarro where mosquitoes enter huts and can be killed by contact or fumigant action on treated walls.

Reactions to Shading in the Sea Urchin, *Psammechinus miliaris* (Gmelin)

IN this urchin, podia withdraw in response to sudden shading. When the aboral hemisphere was subjected to an illumination of 250 metre-candles from a tungsten filament lamp, according to the individual, a 3–20 per cent decrease in intensity proved a minimal stimulus. Most of the podia responded simultaneously when the light was relatively bright; but when dim, or when the shadow was faint, many fewer responded and then at different times.

By using calibrated neutral filters it was found that the interval between instantaneous shading and the appearance of a clearly visible response varied inversely with the intensity of illumination and the degree of intensity change.

In successive experiments with an illumination of more than 100 metre-candles, in response to a 20 per cent decrease, this interval was approximately constant for each individual, but at 5–20 metre-candles it varied considerably. Despite such variations, there was sometimes an indication of adjustment, in that this period decreased in successive experiments under the same conditions.

Urchins must be exposed to light for a certain length of time before they react to shading, the duration varying inversely with the light intensity. Different individuals required 0·5–2·0 min. at 60 metre-candles, and 3–22 min. at 6 metre-candles. The response thus depends, in part at least, on photochemical reactions.

The relative effectiveness of exposure to light in regions of the spectrum between 400 and 560 mμ and between 620 and 700 mμ was determined by means of four coloured filters with known transmission, and a light source of known colour temperature. For this response, using the relative amount of light energy transmitted by the filters as a basis for comparison, the animal appeared most sensitive between 440 and 560 mμ.

The work was done at the Plymouth Laboratory of the Marine Biological Association, and a full account will be published later.

Plastochron Determination in *Ranunculus* using Carbon-14 Dioxide

DETERMINATION of the plastochron, or tim interval between the formation of successive lea primordia, suffers from the difficulty of establishin the age of a primordium at any particular stage c development. An autoradiographic technique ha been successfully used for obtaining an estimate of th plastochron of *Ranunculus* by indirect means.

The technique utilizes differences in amount c active material taken up by young leaves in differer stages of development following administration c carbon-14 dioxide to one of the fully mature leaves Two doses, at an interval of several weeks, are fol lowed by a period in which the adjacent young leave are allowed to grow to maturity. The leaves are the dried and exposed for two weeks to X-ray film allowing the relative activity of successive leaves to b determined. Differences in uptake become evider as peaks of activity separated by a gap of leave with lower activity. From the number of leave between the peaks, the average rate of formatio of successive leaf primordia can be calculated.

Ten plants of *Ranunculus hirtus* B. and S. we grown for four months under fluorescent lighting 500 foot-candles intensity and at a temperature

Table 1. RESULTS OF PLASTOCHRON DETERMINATION IN *Ranunculus hirtus* B. AND S. AFTER LABELLING THE YOUNG PRIMORDIA WITH CARBON-14 DIOXIDE

Time interval	Number of leaves between peaks	Plastochron in days
67 days	5 (1 plant)	13·4
	6 (2 plants)	11·1
	7 (3 ,,)	9·6
	8 (2 ,,)	8·4
	9 (2 ,,)	7·4
	Mean plastochron	9·6 s.e. 0·59

15° C. The second administration of $^{14}CO_2$ was made after 67 days, a further 43 days being allowed to elapse before contact autoradiographs were prepared (Table 1). Under these conditions the mean plastochron was found to be a little less than 10 days.

Chasmogamous Flowering in *Viola palustris* L.

AFTER a short burst of chasmogamous flowering in early spring, plants of *V. palustris*, like those of many other violet species, produce a succession of cleistogamous flowers throughout the summer. Such a change in flowering habit could be associated with changes in day-length, as in *V. fimbriatula* and *V. papilionacea* with which Allard and Garner[1] obtained chasmogamous flowers only in short days and cleistogamous flowers in long days. With several other violet species Chouard[2] has obtained chasmogamous flowering only in short day-lengths (for example, *V. odorata*), or after exposure to winter temperatures (for example, *V. silvestris*), or after both winter temperatures and subsequent short-day treatment (for example, *V. hirta*).

Experiments carried out in the Earhart Laboratory at Pasadena on members of five clones of *V. palustris* gave results that may be summarized as follows. Flower initiation may occur in plants under both short (8 hr.) and long (16 hr.) photoperiods, and also in continuous light. Plants kept in long days at a phototemperature of 20° C. and nyctotemperature of 14° C. (20°/14° C.) produced an abundance of large long-petioled leaves and of even taller peduncles bearing cleistogamous flowers, but never any chasmogamous ones. Plants transferred from long to short days continued to produce cleistogamous flowers for about two weeks: most of them then ceased flowering altogether, although a few plants later bore an occasional chasmogamous flower.

In short days the leaves were much smaller, round rather than cordate, and with short petioles; at 20°/14° C. most of the initiated flower buds did not develop, but nearly all plants produced occasional chasmogamous flowers, never any cleistogamous ones. In short days at higher temperatures no flowers of either kind were obtained, nor any at 17°/10° C. Several of the plants transferred from short days produced a few chasmogamous flowers when first moved to long days at 20°/14° C. before cleistogamous flowering began.

All the plants vernalized for eight weeks at 4° C. in short days of artificial illumination at 400 foot-candles intensity gave a short burst of chasmogamous flowering when transferred to 20°/14° C. in either short or long photoperiods. In long days this initial burst was followed by continuous cleistogamous flowering, in short days by no further flowering.

These results suggest a certain equivalence between short day-lengths and low temperatures in their encouragement of chasmogamous flowering in *V. palustris*, as also in the flowering of winter rye[3], and Chouard's results indicate that in some species the vernalization pathway, in others the short-day path, is the more effective, while in *V. hirta* the joint action of both is usually required. Allard and Garner considered that chasmogamy occurred only in conditions of reduced vegetative expression, which may account for the complete absence of chasmogamous flowers in short days at temperatures above 20°/14° C. where growth was more abundant. On the other hand, the fact that cleistogamous flowering was also absent in these conditions indicates clearly that the flowering habit is not simply an expression of the amount of growth made. Bergdolt[4] found that chasmogamous flowering of several violet species was favoured by a high nutrient supply; but in the present experiment all plants received a balanced nutrient solution every day, yet only cleistogamous flowers appeared in the continuous long-day treatments. Thus the effect of photoperiod on the type of flowering does seem to be specific, and not merely an indirect growth effect. However, the effect of vernalization and short-day treatments on the induction of chasmogamous flowering in *V. palustris* is strikingly ephemeral, few of the buds present during these treatments giving rise to chasmogamous flowers, which does suggest that the specific effects of short days and low temperatures on full flower development may be expressed only within a narrow range of growth conditions.

Control of Watercress Crook Root Disease by Zinc-fritted Glass

CROOK root disease of watercress (*Nasturtium officinale*, R.Br. and *N. officinale* × *N. microphyllum*, Boenn. ex Rchb.) was first reported in 1948 by officers of the National Agricultural Advisory Service. During 1949 the disease was found in all the watercress-growing districts, and it has now reached such serious proportions that it is a major threat to the industry.

The disease was found by Spencer and Glasscock[1] to be caused by a water-borne fungus (probably a species of *Spongospora*) which infects the roots and causes them to become swollen, distorted and 'crooked'. Infected plants lose vigour, become stunted and may eventually die. Investigations, since made by me, indicate that a practical control of the disease may be obtained by the addition of traces of zinc to the water in the watercress bed.

Laboratory studies on the disease were made by growing healthy rooted watercress cuttings in distilled water in glass jars together with watercress cuttings bearing infected roots. The fungus in the infected roots liberated zoospores which infected the healthy roots, the cycle from infection to further zoospore liberation occurring in 8–10 days.

No infection could be obtained, however, when laboratory tap water at the Sub-centre of the National Agricultural Advisory Service, Wye, Kent, was used, although heavy infection was obtained using local spring water. The possible use of zinc in the control of the disease first became evident to me when analyses of the two waters, made by Dr. R. L. Mitchell of the Macaulay Institute, Aberdeen, showed that the tap water contained 1·8 p.p.m. zinc compared with 0·04 p.p.m. zinc in the spring water. The greater amount of zinc in the tap water was apparently caused by its flow through ga'vanized pipes.

Tests were made with zinc sulphate, and it was found that whereas 19·5 per cent of the primary roots and 12·5 per cent of the secondary roots became infected in distilled water, no primary roots and 0·03 per cent of the secondary roots became infected in zinc sulphate solutions containing 0·5 p.p.m. zinc. Infection was completely suppressed at a concentration of 2·0 p.p.m. zinc.

The use of soluble zinc compounds to control the disease in watercress beds presented practical problems caused by the large quantity of water passing through the beds (3–500,000 gallons per acre per day). These led to a search for relatively insoluble materials from which zinc would be liberated very slowly and which could be applied over the whole bed. One such material, a very insoluble zinc-containing glass-frit (zinc F.T.E.), has given promising results under field conditions.

Zinc frit consists of zinc oxide dissolved in glass which is then milled to a fine powder (< 250 mesh).

Composition of zinc F.T.E. (zinc frit) F.N.266

	SiO_2	Fe_2O_3	Na_2O	CaO	ZnO
Per cent	55	4	16	2	23

The material is similar in type, though not in composition, to the fritted glasses used by Wynd[2] for supplying certain trace elements to plants.

Using the laboratory method described above, it was found that an amount as small as 0·05 gm. of zinc frit per 350 ml. water prevented infection. Comparative tests using two other frits, neither of which contained zinc, showed that these gave no control of the disease at amounts up to 0·2 gm. per 350 ml. of distilled water. This indicated that the effect of the zinc frit was due to its zinc content and not to the other constituents of the glass. This was substantiated by the fact that control was also obtained with 0·01 gm. zinc oxide and with 0·18 gm. powdered metallic zinc per 350 ml. of distilled water.

Field tests were then made in which zinc frit and two other non-zinc-containing frits were applied to three separate experimental watercress beds[3] in September 1955. These were treated with frits at the rate of 1 lb. per square yard; similar, adjacent, untreated beds, with common water supplies, served as controls. Zinc frit was also applied to two full-sized commercial beds in March 1956. They were divided longitudinally into three equal areas; the outer strips were treated with 1 lb. and ½ lb. of zinc frit per square yard respectively, and the centre, untreated strip was used as a control.

In all the trials, the plants in the beds were initially heavily infected with crook root. 4–8 weeks after treatments the watercress in the beds treated with zinc frit began to grow more strongly than that in the beds treated with the other frits and in the untreated beds. Very little or no crook-root infection could be found on the roots of the plants treated with zinc frit, whereas the control plants and the plants treated with the other frits remained heavily diseased.

These differences in growth and infection were still apparent eight months after treatment of the beds. The zinc content of the plants in the beds treated with zinc frit was somewhat higher than that of the plants in untreated beds; but the plants were still quite safe for human consumption. The zinc content of the outflow water from treated beds was less than that found to be toxic to fish in hard waters[4], such as supply most watercress beds.

Thanks are due to Messrs. Ferro Agricultural Division, Wombourn, Wolverhampton, for making and supplying the frits used in this study.

Molybdenum Deficiency in Hops

DURING the 1953–54 season, samples of leaves of hops showing chlorosis and breakdown, or a fine white speckling, of the lamina were received from a hop garden on the Motupiko soil type (*p*H 5·4–5·7) at Neudorf, Nelson (Fig. 1). Chemical analysis showed no important differences in zinc, copper and manganese contents between these leaves and those obtained for the many samples examined in this laboratory over a number of seasons. On the other hand, the molybdenum content of the affected leaves was 0·025 p.p.m. in the dry matter, which may be

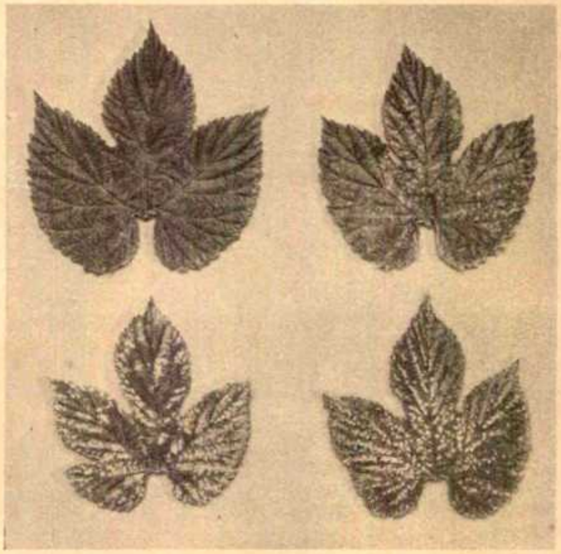

Fig. 1. Hop leaves; healthy leaf, top left; remaining leaves showing various grades of speckling

compared with 0·04 p.p.m. molybdenum for apparently healthy leaves in the same garden, and with the range of values, 0·08–2·1 p.p.m., for samples from other areas. In none of these latter samples was there any indication of abnormality in the leaves.

Because of the possibility that the unusual condition of the plants was due to a deficiency of molybdenum, a trial using sodium molybdate at 0·25 gm. per plant (250 gm. per acre), and ground imestone at 2 lb. per plant broadcast, singly and in combination, was set out on October 21, 1954. During the season, chlorosis and speckling of leaves were noted on a number of plants. By harvest time March 1955), there was a very good favourable response to the molybdenum treatment, plants on plots receiving molybdate being mostly healthy with fresh green leafage. Limestone was beneficial. When used in conjunction with ground limestone, sodium molybdate was not so effective as when used alone. Chemical analysis showed that the improved condition of the leafage was positively correlated with an increased level of molybdenum in the aminæ.

This experiment was continued and enlarged in the 1955–56 season. The original plots, and new plots, were treated on October 25 with sodium molybdate to provide a rate of 1 lb. per acre on all he plots. On December 9 plants on the untreated areas of the original plots were mostly seriously ffected by upward curling of the leaves with brown ecrotic areas about 2 mm. in diameter, which later urned white, with leaves smaller and of a lighter reen colour than normal. Where sodium molybdate was used, very satisfactory plants were produced. The effect of ground limestone was not completely atisfactory. For samples of laminæ taken on Janu- ry 21, 1956, at a height of approximately 5 ft., rom plants of the original series of plots, the follow- ng analytical data (p.p.m. molybdenum) were btained : untreated, 0·12 ; limestone, 0·23 ; sodium molybdate, 1·03 ; molybdate plus limestone, 0·66. lthough many of the plants on the untreated plots were showing severe symptoms, these did not gener- lly extend above 5 ft. from the ground, so that most of the leaves in the untreated samples were pparently healthy.

Molybdenum content of the cones was increased y the use of sodium molybdate. Cones have been ound to be richer in molybdenum than the corre- ponding leaf laminæ on both this deficient and other ealthy areas.

On December 20, 1955, the plants were classified percentages as follows, *H* referring to healthy and to those showing only a trace of leaf symptoms : dium molybdate, 90*H* and 10*T* ; molybdate plus nestone, 67*H* and 33*T* ; limestone, 42*H* and 42*T* ; ntreated, 6*H* and 22*T*. On the plots treated for nly one season, the counts were : molybdate, 89*H* nd 11*T* ; untreated, 25*H* and 33*T*. These results ow how completely the use of sodium molybdate as overcome the ailment, and confirm the diagnosis of olybdenum deficiency as the cause of the symptoms n the leaves.

The Olivine–Spinel Transition in the Earth's Mantle

FROM seismic data, Jeffreys[1] has inferred the presence of a discontinuity in the Earth's mantle at a depth of 400–500 km. Bullen[2] has found that between 400 km. and 900 km., a rapid increase in density occurs. It was suggested by Bernal[3], in conjunction with Jeffreys, that these findings could be explained by the assumption of a pressure inversion in the olivine of the mantle. Bernal suggested that, at high pressures, magnesium silicate might be inverted from an olivine to a denser spinel structure.

The Jeffreys–Bernal hypothesis has been investigated by a thermodynamic study of sub-solidus phase equilibria in the pseudo-binary system Ni_2GeO_4—Mg_2SiO_4 (Fig. 1). At 1,500° C., nickel germanate, which possesses a spinel structure, dissolves 9 per cent of magnesium silicate. From this and other similar data, the molar free energy of transition (F) of magnesium silicate from the olivine to the spinel structure may be calculated.

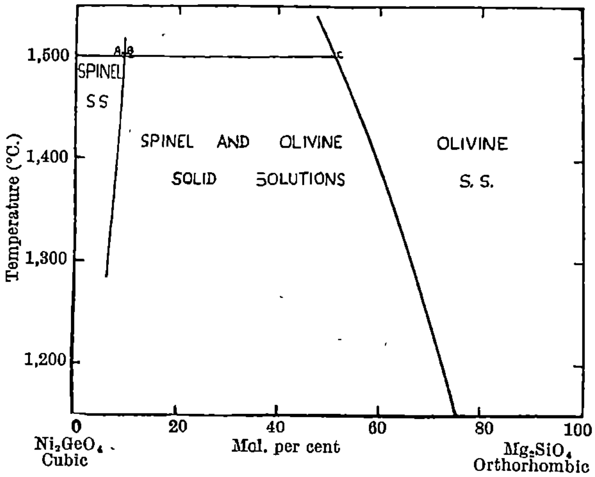

Fig. 1. Sub-solidus phase equilibria in the pseudo-binary system Mg_2SiO_4—Ni_2GeO_4

If a_1, a_2 are the activities of magnesium silicate in the spinel and olivine solid solutions in equilibrium, it is possible to show that:

$$F = RT \ln \frac{a_2}{a_1}$$

Assuming ideality and applying Raoult's law, a_1 and a_2 can be found from the compositions of co-existing phases in equilibrium. (The activity of Mg_2SiO_4 in a solid solution is given[4] by $[Mg]^2[Si]$ and not $[Mg_2SiO_4]$.) On this basis, a value for F of $68,000 \pm 10,000$ joules/mole is found. The accuracy of this result depends upon the assumption of ideality. Theoretical considerations and further experimental work support this assumption.

The density of Mg_2SiO_4 spinel is obtained by extrapolating the densities of Ni_2GeO_4—Mg_2SiO_4 solid solutions. The transition is found to involve an increase in density of 11 ± 3 per cent. This value is supported by analogous studies of the density difference between cubic and orthorhombic magnesium germanate. The function $\int_0^P \Delta v \, dP$, where Δv is the difference in molar volume, may be calculated for different pressures using reasonable assumptions as to the compressibility of Mg_2SiO_4 spinel. This gives the difference in free energy of the two forms due to compression. When this reaches 68,000 joules, spinel becomes the stable form.

Calculation indicates that this value will be reached at a pressure corresponding to a depth of 520 ± 180 km. within the Earth. This is in good agreement with the depth of the 20° discontinuity found by seismology and is considered to provide strong evidence supporting the Jeffreys–Bernal hypothesis.

An olivine–spinel transition in the mantle is capable of explaining the variation with depth of density, elasticity and electrical conductivity. It is consistent also with the inference by Bullen[5] and by Birch[6] that the transition takes place over a wide range of depths. A substantial pressure interval would accompany the transition, because of the presence of other components in solid solution, particularly Fe_2SiO_4, $MgSiO_3$, Ca^2, Al^3, Cr^3. (Spinels are widely tolerant towards ionic substitutions and are often able to dissolve compounds with ABO_3 type formulæ.) The presence of a finite temperature gradient and the possibility of hysteresis and non-attainment of equilibrium also contribute towards a range of transition.

Occurrence of the transition raises difficulties for the convection theory of orogenesis, because of the liberation of latent heat during the transition and difficulties in maintaining equilibrium. However, the contraction theory is considerably strengthened. As cooling causes inversion of olivine to spinel, the volume contraction for the same heat loss is about twenty times greater than the normal thermal contraction.

This communication is essentially an abstract of a more comprehensive investigation[7] the full results of which will be published in due course.

A. E. RINGWOOD

Department of Geology,
University of Melbourne.

[4] Tempkin, M., *Acta Physicochim. U.R.S.S.*, **20**, 411 (1945).
[5] Bullen, K. E., "Introduction to the Theory of Seismology", Chapter 13 (Camb. Univ. Press, 1947).
[6] Birch, F., *J. Geophys. Res.*, **57**. 227 (1952).
[7] Ringwood, A. E., Ph.D. thesis, University of Melbourne (1956).

WITH great interest I have read the preceding important communication by Dr. A. E. Ringwood, which seems to confirm a hypothesis about a phase-transition of the olivine between the depths of 200 km. and 900 km. in the Earth, which I proposed (*Proc. Roy. Netherlands Acad. Sci.*, B, **59**, 1; 1956), starting from a different basis, namely, the overwhelming evidence in favour of convection-currents in the mantle. This demands the same chemical constitution throughout the whole mantle, and so we have to assume a phase-difference between the upper layer, above 200 km. depth, and the lower layer, below 900 km. depth, with a transition-layer between, in order to explain the density results, derived by Jeffreys, Birch and others on seismological grounds.

In this paper I tried to show that all the facts agree to this supposition, if at least the transition energy K per gram is smaller than an upper limit given by

$$\left(\frac{K}{cA}\right)_m \leqq {}_l\theta_e - {}_u\theta_e$$

where the left-hand side is the mean value ove the whole transition layer of the ratio of K t the product of the specific heat c and the hea equivalent A, while ${}_u\theta_e$ and ${}_l\theta_e$, respectively, are th values of the equilibrium temperature θ_e of the tw phases, at the upper and lower boundaries, respectively, of the transition layer. For a value of c of 0·2 (see "Handbook of Physical Constants" by Birch Schairer and Spicer) the value of K derived fro Ringwood's result, namely, $F = 68{,}000 \pm 10{,}00$ joules/mole, would give:

$${}_l\theta_e - {}_u\theta_e \geqq 580° \pm 90°$$

As this value for the difference in temperature a 200 km. and 900 km. depth is acceptable, I canno agree with Ringwood's conclusion regarding th incompatibility of the convection theory of orogenesi with the phase-transition hypothesis here presente

In the paper mentioned above, I had occasion t make the following points. In the first place, th cooling of the Earth must bring about a broa transition-layer between the two phases, whic slowly travels upwards; it now has reached th position between 200 km. and 900 km. deptl Secondly, the presence of convection currents whic in this period of mountain formation we must su mise to rise below the continents, where the radi activity of the sial must cause a higher temperatu than below the oceans, and to subside below th oceans, must bring about a change of the dens phase into the lighter one below the continents, an the reverse below the oceans. This can explain th regressions of the continents during the first peri of an orogenic cycle and the subsidence afterwar in the way indicated by the geological evidenc In the third place, this state of affairs can expla why in general the temperature gradient found belo the ocean floors is about the same as that foun below the continents, notwithstanding the differen of radioactive heat production in the two areas whic might be expected to give a difference in gradien the phase changes indicated must have a contra effect on the gradient at the surface.

I may refer to the paper mentioned for so further evidence in favour of the hypothesis he presented. Dr. Ringwood's paper is a most importa contribution to it, by giving a solid base for t phase-transition hypothesis.

Surface Adhesion and Elastic Properties of Mica

CONSIDERATION of the crystal structure of mic suggests that the strong adhesive forces observ between mica cleavage surfaces may be the same the forces which hold the alumino-silicate lay together in a block of the material. Cleavage occ between two such layers along a plane of potassi ions, and the surfaces so formed may be flat a molecularly smooth over appreciable areas[2]. App ently, both filled and empty potassium ion sites a present on the cleavage plane, but there is lit surface migration or diffusion of potassium ions. This is shown by the following experiment.

A sheet of muscovite mica was partially immersed in a solution containing radioactive cæsium chloride, rinsed and dried. The end of the sheet which had been immersed exhibited a counting-rate (Geiger–Müller counter) of the order calculated for the replacement of a half-filled layer of surface potassium ions by radioactive cæsium ions of the specific activity used, while the undipped end had a much lower activity. After the strip had been exposed to air at room temperature for three weeks, the counting-rates were found to be the same as they had been an hour after immersion. The presence of the surface ions, their ability to exchange with ions in solution, and the negligible diffusion of the ions either over the surface or into the bulk under these conditions is indicated.

If we assume that the adhesion is dominated by the presence of highly polarized potassium ions and the negative charges of their sites in the alumino-silicate framework, the energy required to cleave mica should be primarily that needed to overcome the coulombic attraction. Further, using the Born model for ionic crystals, the elastic properties in a direction perpendicular to the cleavage plane should be deducible from the same electrostatic forces.

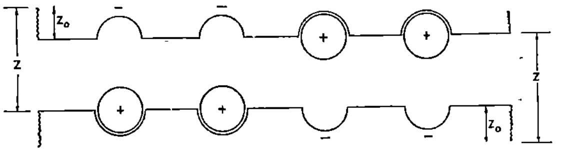

Fig. 1

Using a very simple model (Fig. 1) of potassium ions (+) and neighbouring sites of oxygen bearing a corresponding negative charge, we obtain for the force between a single ion and a single site the resultant of the electrostatic attraction and a repulsive term which decays more rapidly:

$$F = \frac{e^2}{z^2} - \frac{B}{z^n} \tag{1}$$

Since the lateral spacing of the potassium ions and negative sites (about 5 A.) is large compared with z (1·4 A.), only the immediate interaction of ion and site need be considered, that is, the Madelung constant may be taken as unity. Then the energy of separation is given by:

$$E = N \int_{z_0}^{\infty} \left(\frac{e^2}{z^2} - \frac{B}{z^n} \right) \mathrm{d}z \tag{2}$$

where N is the number of potassium ions per cm.^{2} and z_0 is the equilibrium spacing in the crystal (B is determined by the condition $F = 0$ at $z = z_0$). Using $N = 4{\cdot}2 \times 10^{14}$ as calculated from the crystal structure, $n = 7$, and $z_0 = 1{\cdot}4 \times 10^{-8}$ cm. (the radius of an oxygen ion—this is roughly equal to the distance between the potassium ion and the neighbouring plane of oxygen ions), we obtain $E = 5{,}750$ ergs/cm.^{2}. This crude value is within a factor of two of the value obtained by Orowan[3] from Obreimov's data for the cleavage of mica in vacuum. (It should be noted that Orowan computed a surface energy; we have calculated the energy required to effect separation of 1 cm.^{2}, producing 2 cm.^{2} of surface.)

The elastic modulus perpendicular to the cleavage plane is given by:

$$M = N \left(\frac{\Delta F}{\Delta z / z} \right)_{z=z_0} = z_0 N \left(\frac{\mathrm{d}F}{\mathrm{d}z} \right)_{z=z_0} \tag{3}$$

Using equation (1) for F and inserting the values above, we find $M = 2{\cdot}5 \times 10^{12}$ dynes/cm.^{2}. Bridgman[4] estimated the modulus of mica in this direction to be $1{\cdot}7 \times 10^{12}$ dynes/cm.^{2}.

An extension of the adhesion-energy calculation can be made by assuming that in air a monolayer of nitrogen is adsorbed on each side of the cleavage plane. Introducing the dielectric constant of liquid nitrogen and increasing z_0 by twice the thickness of a nitrogen molecule (estimated from the density of liquid nitrogen), we arrive at $E = 618$ ergs/cm.^{2}, or about 309 ergs/cm.^{2} of surface produced. This may be compared with Orowan's value for cleavage and re-adherence in air, 375 ergs/cm.^{2}.

The effect of liquid water in reducing the mica-to-mica adhesion is also readily understood, both the high dielectric constant and the occurrence of hydrogen ion–potassium ion exchange contributing to the reduction of attraction.

While the crudeness of this model and doubts about the accuracy of the experimental data cited make more detailed comparisons unwarranted, the qualitative agreement obtained emphasizes the important role of electrostatic forces in adhesion of mica. The results also indicate the need for more detailed studies of the properties of mica-like materials. It would seem that coulombic interactions can play an important part if the bonding is dominated by a highly polarized ion. In addition, there exists the interesting possibility of exchanging the surface ions after cleavage and so changing the surface properties of the material. Experimental work along these lines is in progress and will be reported elsewhere.

One of us (G. L. G.) acknowledges numerous interesting discussions with Dr. A. M. Bueche and Dr. B. H. Zimm.

Dependence of the Dielectric Breakdown of Transformer Oil on Electrode Conditions

Several workers have found that the breakdown strength of an insulating liquid may be determined not only by its own composition and purity but also by the material and condition of the electrodes used to test it. Recent work in this laboratory is believed to show that the impulse breakdown strength of transformer oil is also dependent upon the thickness of the natural oxide layer on the surface of the electrodes.

Filtered, dried, and degassed oil has been tested in a totally enclosed test cell with micro-second duration impulse voltages of up to 500 kV. Hemispherical electrodes of 2·5 cm. diameter were used at a gap setting of approximately 2·5 mm., and were freshly prepared before each breakdown measurement. After polishing with a soft buffing mop and suitable cutting composition the electrodes were lightly buffed with a clean swansdown mop. This was followed by an examination under a metallurgical microscope to ensure that there were no heavy scratches or pits, after which the electrodes were placed in a desiccator containing a drying agent until required. When the oil had been filtered and degassed the electrodes were placed in position in the test cell, which was then evacuated to a pressure of 10^{-2} mm. mercury before the oil was admitted and the pressure increased to atmospheric in readiness for the test. A series of impulses were applied, increasing in magnitude from a low value in steps of about 1 per cent of the expected breakdown voltage, until breakdown occurred.

The first few tests, for which stainless-steel electrodes were used, gave very erratic results. Further investigation showed, however, that the recorded breakdown strength was dependent upon the time for which the electrodes were stored in the desiccator between the final buffing and their being placed in the test cell. When this time was controlled consistent results were obtained which could be reproduced to within ±2 per cent, but which showed an increase in strength with increasing storage time. Thus tests using electrodes which had been placed directly into the test cell after buffing gave a strength of 1,100 kV./cm., whereas tests in which electrodes which had been kept in the desiccator for more than 5 hr. were used yielded breakdown strengths in excess of 2,000 kV./cm.

Further tests showed that this variation in strength was dependent only upon the treatment of the cathode, and also that the effect was not observed if the electrodes were washed in hexane or acetone after buffing. The same increase in strength was obtained when the drying agent was removed from the desiccator. Tests with aluminium electrodes showed a similar breakdown effect; but in this case the strength varied from 890 kV./cm. for tests with electrodes which had been placed directly into the test cell after buffing, to a constant value of 1,310 kV./cm., when the electrodes were stored in the desiccator for 15 min. or longer. Time lag measurements made during these tests showed that breakdown occurred on or just after the peak of the impulse voltage wave-form.

The only acceptable explanation of the results reviewed above is that oxidation of the freshly prepared surface occurred while the electrodes were stored in the desiccator. The increase in the breakdown strength over a period of several hours when stainless-steel electrodes were used is consistent with results for the oxidation of stainless steel at room temperature, and the steady results obtained with aluminium electrodes which had been left in the desiccator for more than 15 min. also reflect the stable conditions found on an aluminium surface after that time. In order to explain the growth of the natural oxide layer on a metal surface under these conditions Mott[1] has suggested that chemisorption of oxygen on the surface results in a strong field in the oxide, of the order of 10^7 volt/cm., and that this assists the reaction. This theory may be extended to show that under the conditions of the tests described above an electrical double layer exists on the surface of the cathode, the magnitude of which is proportional to the thickness of the oxide. This double layer would hinder the emission of electrons into the liquid and hence reduce the probability of breakdown.

I wish to acknowledge the receipt of a maintenance grant from the Department of Scientific and Industrial Research which enabled this work to be undertaken. It is intended to publish a more detailed account elsewhere.

Photochemical Conversion of Triethyl-tin to Diethyl-tin

DURING the development of a method for the determination of organo-tin compounds[1] it was found that exposure to light of the yellow triethyl-tin–dithizone complex in chloroform produced a rapid change to orange. Examination of the absorption spectra of these solutions has shown that the absorption maxima change from 440 mμ (triethyl-tin–dithizone complex) to 485 mμ (diethyl-tin–dithizone complex) if the complexes are formed in the presence of borate–versene buffer *p*H 8·75. Both the diethyl-tin–dithizone and the irradiated triethyl-tin–dithizone complex change to one with an absorption maximum at 510 mμ upon the addition of one drop 10 per cent alcoholic trichloroacetic acid. Also, triethyl-tin–dithizone, diethyl-tin–dithizone and the irradiated triethyl-tin–dithizone complexes all dissociate upon the addition of one drop of glacial acetic acid to give the spectrum of dithizone. It seems certain that the triethyl-tin–dithizone complex is converted by light to the diethyl-tin–dithizone complex. There is a slow formation of diethyl-tin upon storage on the laboratory bench of a triethyl-tin solution in chloroform, though under these conditions it would take months to effect the conversion obtained in 1 min. in sunlight in the presence of dithizone.

The method for organo-tin compounds[1] estimates only triethyl-tin and diethyl-tin and excludes tetraethyl-tin, monoethyl-tin and stannic ions. After formation of the complexes in the presence of borate–versene buffer *p*H 8·75, absorption at 510 mμ is a specific measure of diethyl-tin in the presence of triethyl-tin. After the formation and measurement of the complexes glacial acetic acid may be added, the complexes dissociated and the total concentration of dithizone measured by absorption at 610 mμ. Quantitative measurements using low concentrations of dithizone (0·00067 per cent) indicates that the irradiation of increasing amounts of triethyl-tin produces increasing amounts of diethyl-tin, and increasing amounts of dithizone are destroyed. Quantitative measurements of the diethyl-tin complex using higher concentrations of dithizone, such that the loss of dithizone does not influence the amount of complex formed for a given amount of diethyl-tin, show that 1 mol. diethyl-tin is produced from 1 mol. triethyl-tin (Table 1).

Table 1

Triethyl-tin irradiated (μm. moles)	Diethyl-tin formed (μm. moles)	$\frac{\text{Diethyl-tin}}{\text{Triethyl-tin}}$
15·8	18·6	1·18
31·6	33·3	1·05
47·3	48·6	1·03
63·0	65·5	1·04
78·8	78·5	1·00

0–20 μgm. triethyl-tin sulphate in borate–versene buffer, pH 8·75 (ref. 1), were mixed with 6 ml. 0·0033 per cent (w/v) dithizone in chloroform. After allowing the layers to separate, the tubes were exposed to sunlight for 10 min., remixed with the aqueous layer, which was then removed and the absorption of the chloroform layer at 510 mμ read against a dithizone control. After reading, the chloroform layers were mixed with 3 ml. of a dilute aqueous solution of 2.3 dimercaptopropanol (this complexes very firmly with diethyl-tin (ref. 2)) and the absorption read again at 510 mμ. This allows a small correction to be made for the loss of dithizone due to the reaction.

These results are consistent with a reaction of triethyl-tin with dithizone to give diethyl-tin and eliminate a possible disproportionation of 2 mol. triethyl-tin to produce 1 mol. tetraethyl-tin and 1 mol. diethyl-tin. All the trialkyl-tin–dithizone complexes so far examined (trimethyl up to trihexyl) are similarly photochemically decomposed. Although there is a very slow production of diethyl-tin from triethyl-tin in chloroform without dithizone, we have no evidence that a neutralized solution of triethyl-tin sulphate in water produces any diethyl-tin upon storage. The liquid tetraethyl-tin slowly liberates triethyl-tin upon storage under laboratory conditions either neat or as a solution in chloroform.

A Method of promoting Water-forming Organic Reactions

THE great reactivity of the boric acid esters with water is well known; moreover, recently even the quilibrium constants of their hydrolysis have been measured[1]. So far as is known to us, hitherto the orates have not been used for promoting water-forming (condensation) reactions.

The basis of our investigations has been to add the esters of boric acid to reaction mixtures which form water during the reaction, in order to hift the equilibrium in the direction of the desired product.

Esterifications were studied first. In preparing the thyl and methyl esters of benzoic acid we observed a marked increase of the reaction velocity with high yields. Then we extended our method to the secondary esters, which are more difficult to prepare. In the presence of 0·11 mol. secondary butyl borate, 0·10 mol. benzoic acid and 0·11 mol. secondary butanol was refluxed for eight hours with 0·2 ml. sulphuric acid. Secondary butylbenzoate was isolated with an 2 per cent yield. In a similar manner, but in the absence of the borate, no ester was formed, the benzoic acid remaining unchanged.

It seemed interesting to prepare the benzyl esters of amino-acids by the same method. It is well known that these esters are important in peptide synthesis, and they are relatively difficult to prepare. In the presence of p-toluene-sulphonic acid[2], in carbon tetrachloride solvent at about 95° the corresponding amino-acid, benzyl alcohol and the benzyl borate were stirred for 4 hr. The p-toluenesulphonic acid salt of the amino-acid benzyl ester is crystallized by further addition of carbon tetrachloride, generally with an 80 per cent yield. Thus glycine, L-glutamic acid and threo-β-p-nitrophenylserine were esterified. Even in the case of glutamic acid the result was satisfactory.

The use of benzyl borates leads to almost quantitative yields in the case of peptides, for example, in the preparation of glycylglycine benzylester.

We have further used this method with another group of compounds in which we prepared acetals and ketals in the presence of borates. Benzaldehyde dimethyl acetal and diethyl acetal can be obtained with about 60 per cent yield. (Without adding the borates the yield is half this value.) The dimethyl ketal of cyclohexanone is prepared with a 65 per cent yield (without borate the yield is 30 per cent), and the diamyl ketal with a 40 per cent yield (without borate no ketal formed). The foregoing tests were carried out under reflux using 1 mol. of the carbonyl compound, 3 mol. alcohol and 1 mol. of borate with a small amount of hydrochloric acid.

This method may be considered useful for promoting other water-forming reactions. Details will be published elsewhere.

A Small Mercury Cut-off withstanding Large Pressure Differences

DURING the course of some work involving the handling of an easily adsorbed gas (ammonia) a number of taps and valves were tried and it was observed that all devices which incorporated greases, plastics or rubber were unsatisfactory owing to the large amount of gas adsorbed by these substances. It was a requirement that the valve for controlling the flow of gas should be vacuum-tight, withstanding a pressure difference between atmospheric pressure and 10^{-3} mm. mercury, have a minimal hold-up of gas and be small and suitable for attachment to a portable piece of apparatus.

The miniature mercury cut-off shown in Fig. 1 was designed and found to be satisfactory. It consists of a 1-cm. No. 4 porosity sintered glass disk *A* which could be immersed in mercury by screwing down on the pressure tubing *B* with a screw clip *C*. This action was made more effective by soldering on the lugs *D* to the cross bars of the clip, giving a larger area of contact on the rubber. It should be possible to raise the mercury by incorporating bellows or a syringe, but the method described was found to be satisfactory and easy of construction.

On filling the valve with mercury, care had to be taken to leave a sufficient gap between the mercury surface and the sinter, since under vacuum this surface rises owing to slight collapse of the pressure tubing.

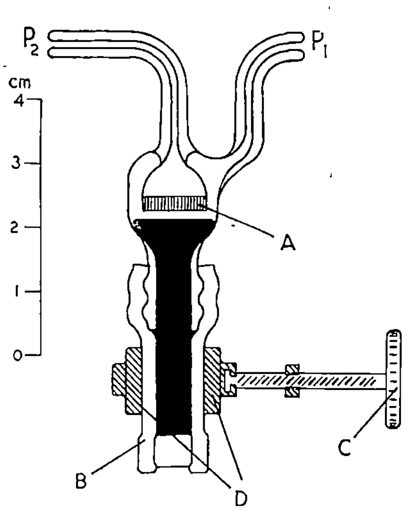

Fig. 1

If the pressure condition $P_1 \gg P_2$ was maintained, the valve was found to be vacuum-tight in the 'shut' position over a pressure difference of an atmosphere.

It was expected that very low pressures for P_2 would not be attainable, as with other sinter devices, but this is not always a necessity.

I thank Dr. V. Gold for much helpful discussion and Mr. H. Lee for help with the glass blowing.

A Theory of Word-Frequency Distribution

The object of this communication is to show that a certain remarkably simple experimental relation governing word-frequencies in language can be explained by a simple model of the process of searching for information, about each word heard or read, in the memory of words employed in the language faculty.

The relation is as follows. If we suppose that $\varphi(\nu)$ is a distribution function giving the number of words in a given vocabulary occurring $T\nu$ times in a given text of T words,

$$\varphi(\nu) = a/\nu^2$$

where a is a constant, is found to be approximately true. This relation was pointed out by Zipf[1] and has been tested by one of us in the case of the Dewey word-count[2].

We now introduce the model which accords with this result, and proceed from the following hypotheses. The first three assumptions concern the process of searching in the memory for information about each word heard or read: (i) when searching for a word, the memory of words is scanned word by word, and only as much of the memory is scanned as is necessary to find the required word; (ii) in this process the words in the memory are scanned in order of decreasing frequency; (iii) the time required to scan a part of the memory of words is proportional to the number of words scanned. The fourth assumption concerns the language in question: (iv) a language will tend to evolve in such a way that the amount of information conveyed per unit of scanning time is a maximum.

It should be made clear that this scanning 'time' need not be physical time—it could be a monotonic increasing function of time: and we could have phrased the set of hypotheses in terms of 'room' occupied in the cortex by the memory of words, so that the average use of 'room' in scanning would be assumed to be minimized.

In order that assumption (iv) may be made strong enough to give a definite answer, we express it in the form that the frequency distribution of access-time is optimal over the whole of a finite range including the actual minimum. This makes the problem one of estimation which can be solved by an adaptation of the method of maximum likelihood. It is in fact reduced to the requirement that the condition, that the average access-time be a minimum, should provide an efficient estimate of the distribution function φ referred to above.

We assume that this function exists and has been correctly estimated, so that the expression for its likelihood will be

$$\lambda = \sum_{w}^{W} T\nu_w \log T\nu_w \qquad (1)$$

where the summation is over all the W words of the vocabulary. We now bring in two conditions: first, that the solution found be independent of the particular choice of vocabulary produced by a given text; this requires that not only the sum (1) but also each of its terms separately should be maximal; secondly, that the access-time for a word w be proportional to the number of words the frequencies of which are not less than ν_w, as follows from assumptions (i)–(iii) above; the access-time can therefore be expressed in the form

$$t_w = \int_{\nu_w}^{\nu_1} \varphi(\nu)\,.\,d\nu \qquad (2)$$

where ν_1 is the frequency in the text of the commonest word.

Now, the conditions postulated reduce to the requirement that the mean of (2) over the whole text and vocabulary be inversely proportional to the likelihood (1), for then the condition of minimum access-time becomes identical with that of maximum likelihood. The resulting equation is

$$\frac{\int_{\nu_w}^{\nu_1} \nu.\varphi(\nu) \int_{\nu_w}^{\nu_1} \varphi(\nu)\,d\nu d\nu}{\int_{\nu_w}^{\nu_1} \nu.\varphi(\nu)\,.\,d\nu} = \frac{c}{T\nu \log T\nu} \qquad (3)$$

One solution of this equation is the given empirica law $\varphi(\nu) = a/\nu^2$ This can be shown by substitution using as a principle of approximation that, except for the first few words, ν_w is small compared to ν_1.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W 1), at 6 p m.—Captain G. T. Smith-Clarke: "Mechanical Breathing Machines" (James Clayton Lecture).

Prestressed Concrete Development Group (in the Lecture Theatre of the Institution of Civil Engineers, 5 Great George Street, London, S.W.1), at 6 p.m.—Prof. D. Vandepitte: "Recent Prestressed Concrete Construction in Belgium".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. A. R. Ubbelohde, F.R.S.: "Users of Power".* (Last of ten University Extension Lectures on "Technology and Industry".)

Friday, December 14—Saturday, December 15

Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom (in the William Beveridge Hall, University of London Senate House, London, W.C 1)—Conference of the Universities of Great Britain and Northern Ireland.

Saturday, December 15

Biochemical Society (in the Department of Biochemistry, St. Mary's Hospital Medical School, London, W.2), at 10.45 a.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physics Graduate in the Department of Radiotherapy, for duties which include physical investigations concerned with the clinical use of rotation therapy, multicurie cobalt units, low voltage X-rays and radioactive isotopes, and also some teaching of radiographer students—The Assistant Administrator, The Churchill Hospital, Headington, Oxford (December 15)

Physical, Analytical and Assistant Chemists at the Central Electricity Authorities' Research Laboratories, Leatherhead, Surrey, for work on problems arising from the generation of electricity in conventional and nuclear power stations—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N/930 (December 19).

Lecturer (Grade I), and an Assistant Lecturer, in Pure or Applied Mathematics at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 21).

Lecturer in Agriculture (Animal Husbandry) at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 21).

Lecturer (with an honours degree or a higher degree in physics, and preferably teaching or research experience) in Applied Physics, at the New South Wales University of Technology, Sydney, Australia —The Agent General for New South Wales, 56 Strand, London, W.C.2 (Australia, December 27).

Professor (preferably experienced university teacher) of Geography at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 28).

Postgraduate Scholar (graduate in veterinary science, science or agriculture) in Veterinary Science—The Registrar, The University, Liverpool (December 29).

Scientific Officer (Chemist) (with a first- or second-class honours degree in chemistry or equivalent, and preferably with experience in mineral analysis, spectrographic analysis, or modern physical methods of inorganic analysis) in the Colonial Office, Mineral Resources Division, London, S.W.7, for analytical and investigational work on minerals and mineral products—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.622/6A (December 29).

J. H. Andrew Research Fellow in Metallurgy; United Steel Companies' Research Fellow in Metallurgy; and Tube Investments Research Fellow in Metallurgy—The Registrar, The University, Sheffield (December 31).

Lecturer (with some teaching experience or experience as a research worker in pest control of plants) in Entomology; and a Lecturer (with a good degree and some experience in plant pathology, either as a teacher or research worker) in Plant Pathology, in the Department of Agriculture, Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (December 31).

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester (January 1).

Lecturer in Organic Chemistry; and a Lecturer in Physical Chemistry—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (January 5).

Research Fellow or Senior Research Fellow in Dairy Science to carry out fundamental research on the problem of depressed butter fat percentage in cattle on certain diets—The Registrar, University of New England, Armidale, N.S.W., Australia (January 7).

Research Fellow or Senior Research Fellow in Poultry Science in the Faculty of Rural Science—The Registrar, University of New England, Armidale, New South Wales, Australia (January 7).

John Elder Chair of Naval Architecture—The Secretary of University Court, The University, Glasgow (January 11).

Drummond Fellows for Research in Nutrition—The Honorary Secretary, Drummond Trust, University College, Gower Street, London, W.C.1 (January 31).

Lecturer in Biochemistry at the University of Malaya, Singapore —The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 31).

Lecturer (preferably with qualifications or experience in structural geology, stratigraphy, or quaternary geology) in the Department of Mineralogy and Geology, University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, January 31).

Reader or Senior Lecturer in Statistics, at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

Robert Blair Fellow (British subject and at least 21 years of age) in Applied Science and Technology, for one year of advanced study or research abroad—The Education Officer (EO/WA.14), The County Hall, London, S.E.1 (February 28).

Assistant Conservators (with a university degree in forestry) of Forests, Sierra Leone—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/15/04.

Hydraulic Engineers (B.Sc. (Eng.), and preferably subsequent experience in hydraulics) in the Department of Mines and Natural Resources—Water Resources Branch, Province of Manitoba, Canada —The Agent General, Province of Manitoba, 8 Spring Gardens, London, S.W.1.

Laboratory Technician (A.I.M.L.T. or equivalent)—The North London Blood Transfusion Centre, Deansbrook Road, Edgware.

Lecturer in the Department of Aircraft Electrical Engineering—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks, quoting Ref. EP/L.

Lecturer (man or woman, with a horticulture qualification and preferably teaching experience) for Rural Science, at the Cheshire County Training College, Alsager—The Director of Education, County Education Offices, City Road, Chester.

Research Student (graduate in physics, engineering or aeronautics) to study the supersonic flow of gas through nozzles—R. P. Fraser, O.B.E., Chemical Engineering Department, Imperial College of Science and Technology, London, S.W.7.

Senior Mechanical Engineer (with an honours degree in mechanical engineering and have held a position of responsibility in engineering research or design) at the Central Electricity Research Laboratories, Leatherhead, Surrey, to take charge of the Mechanical Engineering Section responsible for investigating mechanical performance of materials and components, including static and dynamic stress analysis, vibration analysis, and the effect of fly-ash on the strength of concrete—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. AE.902.

Senior Technician in the Zoology Department—The Secretary, Royal Holloway College, Englefield Green, Surrey.

PERMUTIT

ION EXCHANGE *in the* **CHEMICAL INDUSTRY**

Yet another application of Permutit Ion Exchange is the deacidification of formaldehyde, which is performed by the Permutit plant illustrated here. Increasing numbers of Permutit Ion Exchange plants are now being used to improve and accelerate many chemical and metallurgical operations. Perhaps in *your* industry Permutit can help to improve the product or reduce costs. For full technical information and advice, please write to :—

Drying • • • Incubating • • • Sterilising

This GRIFFIN Modulat Oven has been specially designed to give high thermal efficiency, and distribution of the heating elements assures the rapid attainment of maximum temperature plus low power consumption. A special accelerated thermostat gives considerably improved performance and provides a high degree of thermal stability. The temperature gradient is of the order of ±2° C., with a total loading of 650 watts reaching its maximum temperature of 160° C. in one hour. The heated chamber measures 12 in. by 12 in. by 12 in.

LECTURES AND COURSES

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

Principal: B. V. Bowden, M.A., Ph.D., M.I.E.E.

POST-ADVANCED LECTURES IN PHYSICS

A course of nine lectures on

METHODS AND PROCEDURES IN CRYSTAL-STRUCTURE DETERMINATION BY X-RAY DIFFRACTION

Mondays from 7 to 9 p.m. commencing January 14, 1957.

Organizing Lecturer: Professor H. Lipson, M.A., D.Sc., F.Inst.P.

Fee: £1 10s.

Further particulars of the course and entrance forms may be obtained from the Registrar, the Manchester College of Science and Technology, Sackville Street, Manchester, 1.

CHELSEA POLYTECHNIC

(Provisionally designated College of Advanced Technology)

DEPARTMENT OF CHEMISTRY

SANDWICH COURSE IN CHEMISTRY

A Sandwich Course in preparation for the examinations leading to Graduateship of the Royal Institute of Chemistry will commence in January, 1957. The course will be of four years' duration, and will involve six-months study at College and six-months industrial experience. The normal requirements for admission to the course will be successes at A Level (G.C.E.), or comparable examinations, in Chemistry, together with Physics and/or Mathematics, and three suitable ordinary level subjects.

Inquiries from individual students, industrial firms, research organizations and government departments will be welcomed. Particulars from the Clerk to the Governors, Chelsea Polytechnic, Manresa Road, S.W.3.

UNIVERSITY OF BIRMINGHAM

FACULTY OF SCIENCE

M.SC. COURSE IN RADIOACTIVITY

A course of lectures and practical work in general radioactivity leading to the degree of M.Sc. by examination, is available in the Department of Physics. The course is suitable for honours graduates in physics wishing to obtain special experience in radioactive techniques, including radiochemistry. Graduates in subjects other than physics and graduates who have not obtained honours will also be considered for admission to the course.

M.SC. COURSE IN REACTOR PHYSICS AND TECHNOLOGY

A course of lectures and practical work in reactor physics and technology, leading to the degree of M.Sc. by examination, is available in the Faculty of Science. The course is suitable for graduates with a good first degree in pure or applied science (normally physics, mechanical engineering or chemical engineering). Some introductory lectures and tutorial assistance will be provided to bring entrants to the necessary standard of knowledge in relevant branches of both physics and engineering.

These courses will last for one academic year; the fee is £81. A limited number of maintenance awards with remission of fees will be available in connection with each course. Applications for admission to the courses starting in October, 1957, and requests for further information, should be made as soon as possible to the Registrar, the University, Edgbaston, Birmingham, 15.

Graduates wishing to be considered for the Advanced Course Studentships of the Department of Scientific and Industrial Research must apply to the Registrar before February 1, 1957.

OFFICIAL APPOINTMENTS

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for a Lectureship in Electrical Engineering. Salary £650 by £50 to £1,350 per annum. Commencing salary will be at a point on the scale according to age, qualifications and experience. Membership of the F.S.S.U. and children's allowance scheme.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications (six copies), must be sent by December 15, 1956.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer or Assistant Lecturer in Mathematical Statistics. The successful candidate will be expected to assist in advisory and research work in addition to his teaching duties. Salary scales per annum: Lecturer, £650 to £1,350: Assistant Lecturer, £550 to £650; initial salary and status according to qualifications and experience. Membership of F.S.S.U. and children's allowance scheme.

Applications should be sent not later than January 1, 1957, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

LONDON COUNTY COUNCIL

ROBERT BLAIR FELLOWSHIP IN APPLIED SCIENCE AND TECHNOLOGY

Applications are invited for the award of the Robert Blair Fellowship tenable for one year of advanced study or research abroad in applied science and technology. The value of the award is subject to variation, and, if the country selected should be Canada or the U.S.A., may be up to £2,000 (subject to income tax). Candidates must be British subjects and at least 21 years of age.

Further particulars and forms of application may be obtained from the Education Officer (EO/WA.14), The County Hall, S.E.1 (stamped addressed foolscap envelope necessary), for return by February 28, 1957. (2270)

ROYAL TECHNICAL COLLEGE

SALFORD

APPOINTMENT OF PRINCIPAL

Applications are invited for the appointment of Principal of the Royal Technical College, Salford, as soon as possible. The College has been designated as one of Advanced Technology, and the salary scale provides for a minimum of £2,600 per annum, and a maximum of £3,000 per annum, with annual increments of £80. Candidates should have high academic qualifications and wide experience, preferably including industrial, research and teaching experience.

Particulars and application forms may be obtained from the Director of Education, Education Office, Chapel Street, Salford, to whom completed forms should be returned not later than December 12, 1956.

R. RIBBLESDALE THORNTON,
Clerk to the Governors

Town Hall.
Salford, 3, Lancs.

UNITED OXFORD HOSPITALS

THE CHURCHILL HOSPITAL, HEADINGTON, OXFORD

A Physics Graduate is required in the Department of Radiotherapy, Churchill Hospital, for appointment in the salary scale £710 to £845. The post is expected shortly to be given a Senior Physicist grading with a salary scale £910 to £1,230, and, if satisfactory, promotion would then be made to this grade. The duties include physical investigations concerned with the clinical use of rotation therapy, multicurie cobalt units, low voltage X-rays and radioactive isotopes, and also some teaching of radiographer students. The department is expanding and there will be the opportunity for original work.

Applications, giving full details and names of two referees, should reach the Assistant Administrator within two weeks of this advertisement.

CENTRAL ELECTRICITY AUTHORITY RESEARCH LABORATORIES, LEATHERHEAD, Surrey, require PHYSICAL, ANALYTICAL and ASSISTANT CHEMISTS in an expanding section working on problems arising from the generation of electricity in conventional and nuclear power stations. The problems include the automatic measurement of very low concentrations of impurities in gases, development of rapid methods of analysis of metals and alloys used in nuclear reactors, corrosion at normal and high temperatures in conventional and nuclear plant and the behaviour of inorganic constituents of coal during combustion.

Salaries: Grade 1, £1,175-£1,525 per annum
Grade 2, £995-£1,345 per annum
Grade 3, £930-£1,140 per annum
Grade 4, £735- £910 per annum
Grade 5, £520- £695 per annum

according to qualifications and experience.

Candidates for Grades 1 to 4 should have an honours degree, A.R.I.C. or equivalent, with experience commensurate with grade. For Grade 5, H.N.C. in chemistry or equivalent experience desirable, but not essential.

Applications, stating age, qualifications, experience, present position and salary, to D. Moffat, Director of Establishments, Winsley Street, London. W.1, by December 19, 1956. Quote ref. N/930.

RUBBER RESEARCH INSTITU OF MALAYA

KUALA LUMPUR, FEDERATION OF MALAYA

The Board of the Rubber Research Institut
Malaya invites applications for the post of
of the Statistics Section of the Institute at K
Lumpur. Applicants should have high acad
qualifications and considerable statistical ex
ence. The duties will include design of field
laboratory experiments and conduct of rese
in statistical matters relating to all branche
the Institute's work. The appointment will
made on the Research Officer's scale, the poi
entry being according to age, qualifications
experience. A suitable candidate with the requ
qualifications will be appointed in the upper
(half) of the salary scale which is: basic s
£980 to £1,918 per annum on a time scale
annual increments averaging £46. Superscal
£2,086, £2,254 and £2,506 per annum. A
ances: cost of living and if married in the r
£238 to £391, expatriation allowance for ma
officers £448 to £672. Salary and allowances
paid in Malayan currency. Quarters with h
furniture, medical attention and passages f
wife and two children under 12 years of age
provided.

Application forms and more detailed info
tion may be obtained from the Secretary, Lo
Advisory Committee for Rubber Research (Ce
and Malaya), Imperial Institute, London, S.
to whom completed applications should be
by January 1, 1957.

UNIVERSITY OF ST. ANDREV

The University Court of the University o
Andrews invites applications for either an A
antship in Physiology, or an appointment as T
in Human Physiology, in the Departmen
Physiology and Biochemistry, St. Salvator's
lege, St. Andrews. The Assistantship will b
a period of three years, and the salary £60
£100 to £900 for medically qualified person
not medically qualified and under 26 years of
£550 by £25 to £600; over 26 years of age,
by £25 to £650. F.S.S.U. and family allow
benefits. Six copies of application, together
the names of three referees should be lodged
the undersigned not later than December 21,
The appointment as Tutor, for which a me
qualification is essential, will be for one year
at a salary of £400. The primary duties w
to assist in the teaching of Human Physiology
Biochemistry to medical students, and the
offers facilities for study for a higher qualific
in medicine or surgery. This appointment
date from February 1, 1957.

Further particulars can be obtained from
Professor of Physiology, Bute Medical Build
St. Andrews.

D. M. DEVIN
Joint Clerk to the University C

College Gate,
St Andrews

H.M. OVERSEA CIVIL SERVIC

GEOLOGICAL SURVEY DEPARTMEN

UGANDA

CHEMIST

Qualifications: First- or good second-
honours degree in chemistry. Duties: Analys
ores, rocks and minerals, with particular refe
to the ores of tungsten, beryl, niobium and t
lum, and analyses of limestones: to work in
co-operation with the department's ore-dre
laboratory. Preference will be given to c
dates with experience in such work. Ter
appointment: On permanent and pensionab
contract/gratuity terms with emoluments in
scale £939 to £1,863 per annum. Outfit a
ance. Free passages. Quarters provided at r
Generous leave. Free medical attention In
tax at local rates.

Apply to Director of Recruitment, Co
Office, London, S.W.1. State age, qualifica
and experience. Quote BCD.105/9/06.

UNIVERSITY OF EDINBURG

Applications are invited for the appointme
a Research Assistant in the Department of C
istry, for work on the fundamental chemist
grass conservation. The appointment will be
able for three years. The commencing salar
be in the range £450 to £550 per annum, ac
ing to age, qualifications and experience.

Further particulars may be obtained fro
undersigned, with whom applications, givin
particulars, together with the names of
referees, should be lodged not later than D
ber 31, 1956.

FACTS AND FORMULAE

Your local branch of Smith's can supply you with books on the latest theoretical and technical knowledge, research findings, and the standard reference text-books. If the book you want is not available on demand, it can be quickly obtained for you. Students and college and works librarians are particularly welcome to ask for lists of books on all aspects of Physics.

● *Stationery and printing can also be supplied by your nearest Smith's branch.*

THE ANALYSIS OF MINERALS & ORES OF THE RARER ELEMENTS

Being the Third Edition of the well-known "Schoeller and Powell" and extensively revised by

A. R. POWELL, F.I.M., F.R.I.C., F.R.S.

Contains all the newer analytical procedures including chromatography, polarography, solvent extraction, and spectrophotometry, as well as new gravimetric and volumetric methods

Contents:

Introduction — Mineralogical Analysis — Qualitative Chemical Analysis — Complete Chemical Analysis — Lithium — Rubidium & Caesium — Beryllium — Scandium — Gallium — Indium — Thallium — The Rare-Earth Metals — Titanium — Zirconium & Hafnium — Thorium — Germanium — Vanadium — Niobium & Tantalum — Selenium & Tellurium — Molybdenum — Tungsten — Uranium — Rhenium — The Platinum Metals — International Atomic Weights, 1953 — Gravimetric Factors — Mineralogical Index — Analytical Index.

THIRD EDITION. Reset throughout, 409 pages. (9 in. × 6 in.) ... ... 60s. net.

LIBERAL EDUCATION IN TECHNICAL COLLEGES

THAT formal education in Great Britain must contain more science is now recognized as being necessary and inevitable by nearly all concerned with education. With the recognition goes the quite natural fear that in the process we shall lose some of those virtues which stem from studies based on the humanities. This has recently led to much discussion about ways in which science-based education can be liberalized, culminating in 1955 in the publication of a report prepared as a result of a nation-wide survey by the National Institute of Adult Education*.

The report attracted widespread attention and, in Yorkshire, it was decided to appoint a small working party composed of prominent industrialists and educationists who might give their views on the fundamental issues involved. These views have now been published as a pamphlet which deserves to reach a much wider audience than those members of the Yorkshire Council for Further Education for whom it was mainly intended†. Its true value is that those responsible for it are prominent in their respective fields, and yet came together not as strangers but fully aware of the difficulties confronting their colleagues in industry or education.

From the outset it was agreed that industry urgently needs men whose education is not narrowly restricted to technical matters and that the education given in technical colleges and at universities needs to be made broader and more liberal. While this view was unanimous, the report quickly and rightly describes the strong reaction among technical teachers at both colleges and universities against the tendency of many speakers and writers (usually persons trained in the humanities) to assert or assume that the technologist *ipso facto* is a philistine, who needs an injection of the humanities. The report goes further, and emphasizes that scientific education is a necessary part of cultural education.

Among a number of valuable points made in a section dealing with the teaching of science and technology in colleges is that the introduction of 'arts' subjects into curricula of science and technology is not fundamental to a liberal education. What is required is a broadening of the treatment and presentation of scientific and technological subjects. This ought to be adapted to the age and interests of the students. The approach may be through the history of the craft, a study of the structure of the industry, the philosophy of the subject, human relations in industry, or talks and discussions on industrial design. This approach to the teaching of science and technology could be greatly helped and stimulated by occasional talks by eminent personalities from science, technology and industry, capable of inspiring interest and promoting a further pursuit of this interest by the students themselves.

Ideally, all teachers of technical subjects should have an interest in the historical and philosophical aspects of their subject. Homework should be devised to develop the student's powers of expression, and if English or social history or current affairs is taught separately by a specialist, there should be the closest collaboration between this teacher and the technical specialist. To encourage a wide approach, it is recommended that in as many courses as possible 'liberal' reading should be included each session. To make this realistic, questions based on this 'liberal' reading should be set in college examinations.

Short residential courses for technical students, similar to those which have been held for management students, foremen and local government officers, but not necessarily confined to students in one subject, and dealing with the history and philosophy of science and other suitable topics, could also play an important part in developing the width of view commonly regarded as 'liberal'; this is already common practice in some parts of Britain. Many firms, for example, make considerable use of the general educational courses arranged in residential colleges as a means of 'broadening' their young employees.

It is easy to exaggerate the alleged narrowness of educational provision in British technical colleges. But there are many teachers with a width of outlook who teach their subjects supremely well, of colleges with vigorous music and drama departments, and student activities which compare favourably with those at some universities. Many full-time teachers and most part-time teachers have had no pedagogic training, but nearly all of them have earned, or at present earn, their livings in some job other than teaching, and bring their wide experience to enliven and improve their teaching.

Nevertheless, most teachers in further education are well aware that the techniques of teaching an ever-expanding and changing body of scientific and technical knowledge can always benefit from further study and discussion; it is encouraging that the Yorkshire Council for Further Education is shortly to organize a residential course for heads of departments which will be devoted to discussion of how technical subjects can be taught in a liberal manner. The place in all technical courses of the history and philosophy of science will also be dealt with.

The report recommends that more should be done to encourage travel by students, by making awards tenable at foreign institutions, and that international exchanges of technical teachers should be greatly extended. Much could be done by local education authorities by encouraging teachers to visit other institutions to study teaching methods and organization.

---

* Liberal Education in a Technical Age (Max Parrish).

† The Liberal Aspect of Technical Education. (Yorkshire Council for Further Education.) 2*s*. 6*d*.

The increasing domination of technical college syllabuses by examining and professional bodies is emphasized in the report. Fortunately, their officers often advocate more breadth and liberality of treatment. Extensions of scientific knowledge and new industrial processes, however, and the desire that nationally recognized qualification in one industry shall be as acceptable as that in other industries largely determine the views of industrial members of advisory and examining committees, and undoubtedly exert a narrowing influence. In what ways can this situation be remedied ?

First, the examining and professional bodies themselves could embark upon a bold campaign of re-orientation of syllabuses and review their examination techniques. The City and Guilds of London Institute affords examples of what is already being done. These, if not yet extensive in achievement, point the way.

If some element of history, philosophy, art, economics or human relations is to be included in technical syllabuses, examination papers should include a section on this aspect of the course. If colleges are to be persuaded to make bold experiments in the teaching of science and technology, if attempts are to be made to encourage wider interests, better English, and an appreciation of human affairs and of moral and æsthetic values, these efforts must be encouraged by professional examining committees by treating them as integral to the whole scheme and included in the examination as such.

A considerable section of industry is well aware that many of its problems are human rather than technical, and would welcome the introduction of a broader approach to the teaching of science and technology.

On what lines could industry help to stimulate such a development ? On many advisory committees of examining bodies, attempts to broaden syllabuses and examinations are not greeted with enthusiasm by some industrial representatives. Industrial organizations should see to it that their representatives on local, regional and national advisory committees, and the examiners whose names they put forward, are sympathetic to a really bold and fundamental attack on this problem. In many cases they might consider nominating persons who are near to the personal problems of the industry rather than purely technical officers.

A more immediate and practical step is to help in providing students for 'sandwich' courses and in granting day release where this is not already done. Firms, too, should be encouraged to send their young employees overseas to extend their experience ; this is probably being done to a much greater extent than the committee realizes. The iron and steel industry, for example, has for many years sent large numbers of its younger technical men to steelworks in other countries simply to give them wider experience.

Local education authorities play a large part in the liberalization of technical studies. The part could be much bigger. How many technical colleges, for example, have libraries worthy of the name ? Recent reports on this subject form depressing reading. How many colleges have adequate common rooms for students and staff ? Refectories and facilities for social events are also essential. College surveys suggest that only a small percentage of students participate actively in games and athletics. In planning the new technical education it is important that some provision should be made for physical recreation. Part-time students should take an increasing part in the social and athletic activities of their colleges.

The report stresses the importance of hostel accommodation at colleges with full-time students. A growing number of authorities have already provided hostels and from an economic point of view they may be necessary to ensure that full-time and 'sandwich' courses are filled.

Finally, the report insists that appointing committees, principals and heads of departments should ensure that candidates for posts are made aware that a liberal approach to teaching is expected and will be encouraged ; and that newly appointed teachers are encouraged, and if necessary urged, to take advantage of facilities for adapting their techniques to the needs of an ever-changing world.

The most important duty of the local education authority is the training of teachers, both part-time and full-time. If a new approach, new techniques and a new philosophy of technical education are needed, it is to the training of the right kind of teachers that most attention must be paid.

FERTILIZATION IN ORGANISMS

Fertilization

By Lord Rothschild. Pp. ix+170+5 plates. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1956.) 18*s*. net.

FERTILIZATION, by which is meant the spermatozoal activation of an ovum, with the subsequent fusion of the male and female pronuclei, has always been one of the most enthralling topics of biological study. Lord Rothschild's monograph takes the subject up to the formation of the zygote, but focuses mainly on the changes which take place during the phase of activation. The opening chapter deals with the visible changes of fertilization in various plant and animal forms. The next three are concerned with the fact that the spermatozoa and eggs of many animals and plants incorporate substances, sometimes called gamones, which have specific effects on the gametes of the opposite sex. Among the many topics dealt with in this section of the book are the reciprocal induction of spawning (for example, the spawning of a male sea-urchin may incite every other male urchin in a tank to start shedding its spermatozoa) ; the possibility that water in which the eggs of certain species are maintained may, in certain circumstances, stimulate increased metabolic activity in spermatozoa ; the immunological and chemical nature of different gamones ; and also the principles underlying the chemotaxis of spermatozoa towards the eggs, a process which occurs in certain species of plant, such s ferns, and in which chemical substances that diffuse rom the eggs into the surrounding medium exert an ttraction on spermatozoa. The fascinating idea merges that sperms which are subject to chemotaxis ossess "sense organs not fundamentally different rom those which cause a moth to fly towards a light".

The two chapters that follow deal with the meta-olism of eggs, particularly with the sources of energy vhich permit of the various changes that take place uring fertilization. Here the discussion is focused n the eggs of the sea-urchin and oyster, in which here are both anaerobic and oxidative pathways by vhich carbohydrate is broken down. A variety of etabolic changes of a different kind are listed and ummarized in the following chapter, which precedes n account of other changes that occur in the egg at ertilization, including changes in the birefringence nd tension of the cortical zone. The processes which hibit polyspermy are dealt with in a chapter on heir own, Lord Rothschild holding, as a tentative ypothesis, that "at the moment of attachment of he fertilizing spermatozoon to the egg surface, a hange in cortical structure passes over the egg" vhich "reduces the chance of refertilization by a actor of twenty and catalyses the production of a perm-impermeable layer at the egg surface". This mpermeable layer is established in about sixty econds, and its integrity depends, *inter alia*, on the xistence of divalent cations in the external medium. he subject of polyspermy is followed by a short hapter which summarizes certain bio-electrical bservations that have been made on the egg at rtilization, but which so far have revealed little of nportance, except that there is an increase in nembrane capacitance when sea-urchin eggs are rtilized. Lord Rothschild tells us that there is othing new to say about the specificity of fertiliza-ion, and he concludes his book with a final chapter hat lists fifteen subjects which, in his view, would epay further investigation.

There is a general index of subjects discussed, as ell as an extensive references and author index. articular attention is paid throughout to the orrect systematic designation of the plants and nimals that are referred to, and a separate index rovides synonyms and vernacular names for the ifferent species. The general biologist might have een further helped if the author had also included summary indicating which plant and animal types ad yielded what kind of information about the echanisms of fertilization. A great deal of our resent knowledge is apparently derived from work on chinoderm eggs, and it would have been helpful to now how well or widely based are the more important eneralizations that relate to the subject.

The book is concise, but is so well constructed that is always lively and readable. It is also scholarly nd critical, and the author, who is a distinguished orker in the field, does not disguise the fact that on ertain subjects his opinions are not shared by other nvestigators—although the arguments are marshalled such a way that it is difficult for the non-specialist doubt any of the conclusions that are stated. This partly because the author's approach to his subject-atter is admirably clear-cut, and because the eader is not allowed to forget that what is discussed lates to carefully formulated questions. "The most e can do," writes Lord Rothschild, "and all we need do, in describing some biological problem, is ltimately) to make a time-sequential analysis of the henomenon in the language of physical chemistry." This view may define the field of biology more rigidly than some biologists would like, but there can be no question that, having defined it in this way, Lord Rothschild pursues his theme with the strictest regard for scientific discipline—by asking real questions; by stating real answers when they have been found; and by acknowledging, where necessary, difficulties and ignorance. He provides no addition to the many theories of fertilization that have been advanced by other workers. But he goes one better by ending his story with a clear statement of the more important issues that call for elucidation before a new general hypothesis need be formulated.

S. ZUCKERMAN

AUTOMATIC DIGITAL COMPUTERS

Automatic Digital Calculators

By Dr. Andrew D. Booth and Dr. Kathleen H. V. Booth. Second revised edition. Pp. ix+261. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1956.) 32*s*.

Automatic Digital Computers

By Dr. M. V. Wilkes. Pp. x+305+9 plates. (London: Methuen and Co., Ltd., 1956.) 42*s*. net.

It is only natural that the above two books should cover to some extent the same ground. The first of them has clearly proved its worth by having exhausted its first edition in some two and a half years, a fact which shows without further comment that a need existed for such a book, and that it met that need. As for its main contents, they have been sufficiently described and criticized by the present reviewer in *Nature* (175, 484; 1955), and there seems to be no necessity to alter or amplify what is said there. But in fact the book has been increased by a fair amount of new material, notably the description of the transistor and what it does, in the middle chapters (9, 10 and 11), and of automatic programming procedures as lately introduced, this forming a supplement to Chapter 16. There is also a description of ferro-electric matrix storage. Some idea of the amount of work published on automatic digital computers in the past three years or so is given by the more than doubled bibliography, which now extends from p. 235 to p. 244. The book, as before, can be recommended as clear and painstaking.

The second book is by the well-known director of the Cambridge University Mathematical Laboratory, and, though he gives generous and extensive acknowledgment to others, bears on every page the impress of his own hand. It begins, as it almost necessarily must, with the historical summary—Babbage, Georg and Edvard Scheutz, and so on—and moves quite quickly and naturally from this to the *ENIAC* and *EDVAC* computers. In the most thorough manner we then have the principles of logical design, leading to the principles of programme construction, by which time we are well under way. Chapters on relay computers, storage, electronic switching and computing circuits follow, concerning which it can only be said that the reader is led on in the most natural manner, and with excellent plates and tabular illustrations.

Much the most interesting chapters to the present reviewer are Chapter 7, on the design and operation of digital computers, and the five-page appendix, "Machinery and Intelligence", which is to be thought of as a short chapter. It would seem that Chapter 7, with all that it says about organization, staffing, business purposes and industrial processes, is likely to be the one of most general value in the whole book.

As for the appendix, with a certain relief the present reviewer discovers the last clause of the final sentence to be: "but I do not see them [namely, the machines] behaving like human beings". Neither do I; if ever I see a machine looking in at the door at me, and complaining at having been unsuitably programmed, I shall take suitable consultation, not about it, but about myself.

A. C. Aitken

PLANT EVOLUTION

Features of Evolution in the Flowering Plants

By Prof. Ronald Good. Pp. xv+405. (London: Longmans, Green and Co., Ltd., 1956.) 30*s*. net.

The evolution of the flowering plants is probably as great a mystery as it was a century ago, and it deserves much more critical consideration than it has hitherto received. The study of the problem now presented by Prof. Ronald Good should interest both botanists and a wider public. Those who study plants from any aspect, taxonomic, structural or physiological, can scarcely remain indifferent to the problems of the origin and evolutionary development of the plants which form the major part of the surface vegetation of the world to-day, and of which some 250,000 distinct species are recognizable. At the same time, these problems affect a wider range of studies, since the flowering plants form the ultimate source of nutrition of almost all the terrestrial animals.

At present we have very little, if any, idea as to how these forms have evolved, and Prof. Good does not attempt to present theories or speculations on how they have come to be as we see them to-day. Instead he gives a view of the group "primarily as an achievement of those processes which are called evolution". He briefly surveys the vast number of living types, indicating the general relationships between the principal groups recognized by taxonomists from a study of their floral characters. Then, selecting a large and distinct family of Dicotyledons, the Asclepiadaceae, he examines it more closely to show how evolution has expressed itself within a relatively isolated family. He discusses the difficulties which arise when we try to envisage the course and possible causes of evolutionary differentiation in this series of plants, which have a most remarkable mode of pollination. He next considers the appearance of floral aggregation in many different families, and goes on to survey the flowers of the Compositae, in which floral aggregation is most marked, and may have contributed to making this family the largest and most widely distributed group to-day. This leads to the consideration of superficial resemblances of many kinds between different plants which are apparently quite unrelated, demonstrating "that evolutionary repetition of this sort has been a feature in the history of these plants". The concluding chapter is a summary and discussion of the problems which have been presented.

Prof. Good has shown very clearly how difficult it is to explain the appearance of such a great variety of organisms in terms of the ideas advanced by different writers since Darwin. But he seems to view the question almost entirely from the aspect o floral structure and the mechanism of reproduction and from this aspect close study seems to raise more problems than it solves. Near the end of the book the author recognizes the possibility that the fact may be susceptible to some explanation other than the idea of gradual transformation. He does no suggest what other explanations there may be, bu some readers may well feel that little progress will be made until we know more about the biochemica constitution and the vital processes which go on during the life of the plant. May it not be the physiological make-up, rather than the structura characters, which determines survival and is responsible for evolutionary changes that have occurred in the group during many millions of years in a world where climatic and environmental changes have constantly taken place?

This stimulating book could have been improved by giving the reader more help to understand th illustrations. Few ordinary persons are familiar with the floral structures in the Asclepiadaceae, and the text would be followed more easily if the drawings had been labelled and more fully explained.

H. Hamshaw Thomas

COLLECTED WORKS OF LUDWIG SCHLÄFLI

Ludwig Schläfli, 1814–1895

Gesammelte Mathematische Abhandlungen. Herausgegeben vom Steiner–Schläfli–Komitee der Schweizerischen Naturforschenden Gesellschaft. Band 1: Pp 392. 56.15 Swiss francs. Band 2: Pp. 381. 56.1 Swiss francs. Band 3: Pp. 402. 59.30 Swiss francs (Basle: Verlag Birkhäuser, 1950, 1953 and 1956.)

During his long life (1814–95), Schläfli contributed in many ways to the algebra, geometry and analysis of the nineteenth century. Yet hi influence on geometry might have been much more considerable had the length of one of his greates memoirs not prevented its publication at the time o its production in 1852; this is the famous "Theorie de vielfachen Kontinuität", first made public in 1901 It occupies 220 pages in the first of the present se of volumes, and not unnaturally overshadows the rest of the contents of that volume. Essentially, it i a systematic essay on the extension of familiar metri properties of three-dimensional space to space of dimensions. The first section deals with linear space and the configurations bounded by them, leading u to the study of the regular polytopes, a topic whic has been developed on the basis of Schläfli's work b a number of contemporary mathematicians, and i particular by Coxeter. The second section discusse the hypersphere and its geometry, with speci reference to the spherical simplex and its connexion with the regular polytopes. The final section contain generalizations of quadric properties and relate topics. Had this paper appeared in 1852, would i have had any substantial effect on the general lin of geometrical development during the next hal century? Would the flow of effort on projective line have been deflected, and would Cayley have promulgated his famous phrase of 1859: "projectiv geometry is *all* geometry"? Possibly Cayley did nc intend this to be taken as literally as it often ha been taken; in any event, his line of thought wa not very far removed from that of Schläfli, for whom Cayley had a high regard—enough for him to undergo the labour of translating some of Schlafli's papers into English so that they might be published in Britain.

Volume 2 is mainly on algebra and geometry. The particular gem, by which Schläfli's name is perhaps best known, is the theorem (1858) of the 'double six', concerning the intersections of two pairs of six lines in space. This occurs in a memoir on the classification of cubic surfaces, for the double six configuration is closely related to the twenty-seven lines on the cubic surface. But the theorem does not depend on the theory of the cubic surface, and many other proofs have been given; a melancholy interest attaches to the ingenious proof which relates the result to the celebrated theorem of Miquel on the foci of a set of parabolas, for this was devised by the brilliant young English geometer, Wakeford, shortly before his death on the Western Front in 1916.

Analysis occupies most of the third and final volume. There is, for example, a paper which has the air of being much more modern than its date (1875), in which the asymptotic expansions of the Bessel functions of the third kind are investigated; Watson remarks that this does not appear to have received the attention it deserves. Another paper of importance deals with spherical harmonics. Heine had unsuccessfully attempted to give appropriate definitions of the general harmonics $P_n{}^m(\mu)$, $Q_n{}^m(\mu)$ for complex values of m and n; Schläfli solved the problem for the zonal harmonics ($m = 0$), by means of single-circuit integrals. The general problem was solved somewhat later, by Barnes and Hobson independently, the former using single-circuit integrals and the latter double-circuit integrals of the Pochhammer type.

In spite of some early struggles, Schläfli seems to have had a quiet and happy life, winning the affections of many generations of pupils, and contributing substantially to the pure mathematics of his time. These three volumes, beautifully produced by Verlag Birkhauser, and well edited with sound but unobtrusive comments by Kollros, Burckhardt and Hadwiger, are an appropriate memorial to Schlafli's versatile, polished craftsmanship.

T. A. A. Broadbent

PLANETARY NEBULAE

Gaseous Nebulae

By Prof. L. H. Aller. (International Astrophysics Series, Vol. 3.) Pp. xvi+322. (London: Chapman and Hall, Ltd., 1956.) 63*s*. net.

I HAD hoped on opening this book to find that it dealt chiefly with the diffuse gaseous nebulae, which during recent years have become of special nterest because of their connexion with interstellar matter and the problems of radio astronomy, with the formation and existence of the hot Population I tars, and through these with important problems of the history and structure of the Milky Way. Although "Gaseous Nebulae" indeed devotes some attention to these objects, its chief concern is with the planetary nebulae, and we are informed that Prof. Lyman Spitzer is at present preparing a book on interstellar matter and the diffuse nebulae. Topical interest in the planetary nebulae (which have nothing to do with planets) is less intense, although for more than half a century they have offered fascinating problems to both theoretical and observational astronomers. They are an order of magnitude smaller than the diffuse nebulae, each is centred on a hot star; although often complicated, they show regularities of shape approximating to spheroidal shells, or rings, or even helices; they appear to belong to Population II, and they have no close connexion with interstellar matter.

Nevertheless in some respects, for example, in their spectra, these two distinct classes of nebulae have much in common. Both consist of highly rarefied gas, giving a bright line spectrum, with a considerable number of 'forbidden' lines. The spectrum is produced by a fairly well understood mechanism of ionization, recombination and electron collision, dependent in the first place on dilute ultra-violet radiation from one or more hot stars. But although the general operative principles are known, detailed calculation of the spectrum, or of the physical conditions within the nebula, leads to most formidable complexities. Further, the best observers and the most powerful telescopes are unable with present techniques to give the theorist much of the information which he knows to be of vital importance, and he is too often reduced to forcing a way through his problems by the aid of drastic and not always very convincing simplifications.

Prof. L. H. Aller is a well-known expert in planetary nebulae and here we have a book by an enthusiastic specialist, for specialists. According to the preface, it is based on a much-revised manuscript twelve or more years old. I suspect that the core of the book, Chapter 4 ("Physical Processes in Gaseous Nebulae") and Chapter 5 ("The Forbidden Lines"), which also appears to be the most carefully written part, comes from this manuscript. The other chapters, dealing with types of gaseous nebulae, methods of observation, distances and dimensions, the spectra, the illuminating stars, the structure and internal motions, and the diffuse gaseous nebulae, contain a great amount of very varied and detailed information, too much for clarity, and seem to me to need more thought in arrangement and selection. The specialist, already well acquainted with the subject, may be able to browse with profit, doubtless annotating liberally as he goes. Reading critically and adding much from his own experience, he will realize once more the complexities of the subject, the weaknesses and difficulties of current theories, and the points at which more measurements are urgently needed. He will also find new and hitherto unpublished material, and will be provided with much food for thought.

But it seems to me that the less-advanced student, or the inquirer from another branch of physics, will find complicated matters presented too briefly. He is likely, too, to have difficulty in seeing the wood for the trees and may find himself somewhat bewildered. I cannot recommend the book for such a reader, unless he has a well-informed mentor near at hand to provide a running commentary of elucidation, for there is much which cannot be properly understood without a very wide knowledge of both theoretical and practical astrophysics. Even then, many questions will remain unanswered, some of them pointed out by the author, some not.

There are a number of misprints, including three curious examples on pp. 17, 20 and 229, respectively. Long and useful bibliographies are provided at the end of each chapter.

R. O. Redman

Supplement to the Dictionary of Gardening

A Practical and Scientific Encyclopædia of Horticulture. Edited by Patrick M. Synge. (Royal Horticultural Society.) Pp. x+334. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 42*s.* net.

THIS supplementary volume, published five years after the main work, is in two parts. The first contains the promised lists of recommended varieties of flowers, fruit and vegetables, and also a valuable article on fertility and infertility in fruit. The second, and rather larger, is "Additions and Corrections".

With a compilation of this nature, it must be very difficult indeed to decide when to call a halt to revisions and commit to press, and some matter must inevitably be out of date even when it appears. Also, varieties of cultivated plants are so numerous and multiplying so rapidly that it would be unfair to expect recommended lists to be entirely up to date, comprehensive, or really satisfactory to the specialists in any particular group.

Nevertheless, it is disappointing to find columns of bare names (for example, vegetable marrow), quite misleadingly fragmentary selections (for example, *Primula*, hardy), and many lists like trade catalogues in which several varieties share paraphrasings of one description, with few references to distinctive virtues, and even more important, vices. Many omissions are obvious. Where, for example, are the 'Cambridge' strawberries and brussels sprouts, or the Pacific strain of delphiniums? Yet space is devoted, in an already over-bulky horticultural reference work, to such things as detailed variation within the *Alchemilla vulgaris* aggregate.

The list of contributors to Part 2 is a guarantee of the solid worth of many articles. A more critical selection of genuinely horticultural matter is desirable when the supplement is itself revised and re-issued.

S. CLAY

An Outline of Atomic Physics

By Prof. Oswald H. Blackwood, Thomas H. Osgood and Prof. Arthur E. Ruark. Third edition. Pp. x+501. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 60*s.* net.

FOR the third edition this well-established introduction to atomic physics has been completely rewritten, and the main advances in the subject up to about 1953 are very lucidly explained. The treatment is chiefly descriptive, but the authors give a good elementary outline of what wave-mechanics is about and indeed discuss in some detail the difficulty of arriving at a theory of the deuteron. The account of cosmic rays and of the new particles discovered in this field is fuller than anything which has yet found its way into books of this standard. The final chapter on the Michelson–Morley experiment and the development of relativity theory is also very good.

Little is said about the fascinating subject of ferromagnetism, and the few lines devoted to this are rather confusing; also, it is hard to interpret the statement on p. 76 that electromagnetic radiation is the common carrier that transmits energy between electrons and nuclei. But the marks lost for these minor points are recovered (with a handsome bonus) for the treatment of the elementary particles, for the "model for visualizing their spins, charges, and masses", and for the clear explanation of the concepts of statistical character and parity. A number of problems, complete with answers, and a list of references for further reading are provided.

The preface states that the original aim of the book was to equip non-specialists to keep abreast of current progress in physics; in this it should be most successful.

G. R. NOAKES

Introduction to Chemical Engineering

By Walter L. Badger and Prof. Julius T. Banchero. (McGraw-Hill Series in Chemical Engineering.) Pp. ix+753. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 71*s.* 6*d.*

THE heading of this book should surely be "Badger and McCabe's Elements of Chemical Engineering, third edition revised and enlarged by W. L. Badger and J. T. Banchero", for this is what the book is, in spite of the change of title and authors. A large proportion of the letterpress is identical with that in Badger and McCabe's second edition, both books have sixteen chapters with similar titles and many of the illustrations in the older work appear in the new volume with very minor alterations, made perhaps to substantiate the claim in the preface that "the illustrations have all been specially drawn for this book"; and yet the earlier book is not even mentioned.

Some superfluous matter has been omitted, and nearly all the chapters have been enlarged and brought up to date, especially those on evaporation, distillation, extraction, humidity and gas absorption; and the book retains the valuable characteristic of emphasizing the importance of plant and its constructional details. The problems and worked-out examples are nearly all new. In order to maintain the same thickness and reduce the weight, the paper is now thinner and the lines longer and closer together, allowing an increase of about 35 per cent in the contents. Some of the diagrams are not up to the standard usually found in this series, and the general appearance and clarity have suffered.

In spite of these minor defects, there is little doubt that the book will continue to enjoy the popularity of its predecessor of 1936, which in those days was generally regarded as the Bible of the chemical engineering student.

H. E. WATSON

The Planet Venus

By Patrick Moore. Pp. 132+8 plates. (London: Faber and Faber, Ltd.. 1956.) 15*s.* net.

THE publisher's note about this book states that it is the first serious book in any language devoted to Venus. This is not surprising, as so little is known about the physical conditions on Venus; even the period of its rotations is not known with certainty. But this book is disappointing in many ways. Space is given to the discussion of such matters as the canals of Venus, which are based on observations that are discredited, and of the ashen light, which is a purely instrumental effect, being never observed with reflecting telescopes but only with refractors that are not perfectly achromatic. In some other respects the book is quite inadequate. For example, there is no discussion of the polarization curve; no reference is made to the variation of polarization over the disk or of the appearance and disappearance of areas of abnormal polarization. Such observations have an important bearing on the nature of the atmosphere of Venus and of the clouds in its atmosphere. As an account of the present state of knowledge about Venus, this book cannot be recommended.

H. SPENCER JONES

J. J. THOMSON*

By Sir GEORGE THOMSON, F.R.S.
Master of Corpus Christi College, Cambridge

JOSEPH JOHN THOMSON was born on December 18, 1856, in a suburb (Cheetham) of Manchester. His father was a bookseller and publisher, specializing in old books, and the family was of Scottish origin. He came to be very well known to the Royal Institution, where he was non-resident professor of physics, and he often gave the Friday evening discourse.

To the student of physics of the present day he is known as the discoverer of the electron. Actually that word was coined before his work on the subject began and he preferred to use another; but as I hope to make clear, he did more than any other single person to prove the objective existence of the entity we call by that name, and to provide the theoretical ideas on the subject with experimental proof. But he was not a man of one discovery, and I wish to bring up in rapid review as many as I can of the departments of physics in which he was interested, and which sometimes were connected by unexpected sequences of ideas.

He started as a mathematician—he was second wrangler when Larmor was senior—and his earliest important work was as a disciple—he was never the pupil—of Clerk Maxwell. Maxwell's theory of electricity was not well appreciated when it came out in 1873. It was indeed rather obscure, since the physical conceptions underlying Maxwell's ideas did not appear clearly in the final mathematical form he adopted. 'J. J.', as he was always known, developed the consequences of the theory and showed in particular that a moving charged sphere had additional mass as a result of its charge—the first hint of Einstein's $E = mc^2$—and that the electromagnetic waves carried momentum as well as energy along their rays.

Then he became interested in vortex rings, of which smoke rings are a good example. Vortex rings appealed to nineteenth-century physicists, notably to Kelvin and to Helmholtz, as a possible explanation of atoms, because of their permanence. "It is indestructible and indivisible, the strength of the vortex ring and the volume of liquid comprising it remain for ever unaltered, and if any vortex ring be knotted or if two vortex rings be linked together in any way, they will retain for ever the same kind of be-knottedness or linking." So when vortex rings were set as a subject for the Adams Prize, 'J. J.' took up their theory, and the prize-winning essay published in 1883 contained some interesting suggestions as to the way in which vortex atoms might link together to form molecules. Two, three, four, five or six can be linked together in a special way, but seven or more are unstable.

This early and forgotten theory led 'J. J.' to his earliest experiments on gaseous discharges, the subject he was to make peculiarly his own, and which was to occupy his attention into advanced old age. The connexion may not be obvious, but the theory indicated that the electric discharge in a gas would be associated with dissociation of the molecules in a measurable fashion. The experiments were not in fact, very conclusive, but they led Thomson on to study other properties of the gaseous discharge, and especially the electrodeless discharge, for which he retained a life-long affection. More important than the results obtained was the experience with this kind of experiment, which was so useful to him later on.

The discovery by Röntgen of X-rays in 1895 is a turning point in physics. 'J. J.' was quick to take advantage of it and he and Rutherford showed—about the same time as some other workers—that the X-rays made a gas conducting, thus providing a manageable method of ionization, a word they used in their paper. We shall see how valuable this was in the discovery of the electron.

The fundamental importance of the electron, as was fully realized at the time, is the proof that all matter contains at least this one common constituent, and that the atoms of nineteenth-century chemistry are not separate independent entities, as was then generally supposed.

The actual approach to the electron, the first of the common constituents, came from two different directions, neither of which seemed at the time to have much to do with the structure of the atoms of ordinary matter. Faraday's laws of electrolysis early in the century had produced very strong evidence, which one now feels that the men of the time were very dense in ignoring, that electricity is somehow done up into units of which one, two or three, rarely more, may be attached to each individual atom. Towards the end of the century people woke up to this, and Johnstone Stoney coined the word 'electron' for this hypothetical unit; but as yet it had no other properties. Its magnitude could be estimated, though only very crudely. There was no evidence that it existed alone, apart from electrified matter. It might just have been a unit of exchange in Nature's bank, like the 'money of account' in those countries where the unit of accountancy corresponds to no actual coin.

There were electron theories of a kind in the nineteenth century, but the first that led to anything of importance was that of Lorentz in the early 90's, which immediately explained the discovery of Zeeman in 1896 that the spectrum of the light from a sodium flame was modified by a magnetic field. It is interesting to recall, here in the Royal Institution, that Faraday's last recorded experiment was an unsuccessful attempt to detect this, and that Zeeman, who had read Faraday's work, was deliberately repeating it with more modern equipment.

The other line of approach, in which 'J. J.' was the leader, was given by cathode rays. These can be observed when an electric current goes through a very rarefied gas. They are more familiar to-day, in a slightly modified form, as the working medium of a television tube. They had been known from the middle of the century and their nature hotly disputed. The question became international; on the whole the British and the French held the view that they were some sort of particle, whereas the Germans thought that they were waves and more akin to light. Of course, both were right, but the reconciliation was to come much later.

---

* Friday Evening Discourse at the Royal Institution delivered on December 7.

Cathode rays are deflected by a magnet as a stream of electrified particles would be, and Perrin showed that if shot into a box they gave it a negative electric charge. 'J. J.' combined these two experiments and showed that the magnetically deflected rays took their charge with them. More important, he showed that the deflexion was the same for all rays produced by a discharge of the same voltage whatever the gas and the material of the cathode. This experiment, which was published in February 1897, convinced him, I think, that they were not just 'electricity', whatever that mysterious entity might be, but part, and a fundamental part, of matter as well.

But more was needed, for there were serious difficulties. Hertz had found that they were not deflected by an electric field as charged particles ought to be, and Lenard at Heidelberg had found that they would go right through a thin metal window into the air outside. This seemed impossible if they were charged atoms—and no one had thought of any smaller particle.

The dramatic occasion was a discourse in the lecture room of the Royal Institution, given on April 30, 1897. After showing the modified Perrin experiment and photographs of the deflected cathode rays, he passed to the matter of the missing electric deflexion. The observation, though right in itself, was misleading. When the field was applied (as the experimenters thought) nearly all of it was neutralized by charges produced by the rays themselves in the rarefied gas, so that the region where the rays actually went was devoid of field. The charges do not neutralize magnetic fields, hence the curious discrepancy. 'J. J.' managed to get the vacuum better and found a deflexion by electric fields. Later on he used this deflexion balanced against a magnetic field to find the ratio of the charge to the mass of the particles and their velocities in a way described in every text-book of electricity; but actually on that evening he described another way of measuring the same quantity in some ways more direct. He measured in fact for certain rays their magnetic deflexion, and the heating effect that corresponds to the transport of a unit of charge. In terms of symbols, the first gives e/mv and the second e/mv^2, from which e/m and v can be found. Now e/m is a critical quantity. The Faraday experiments had found it for ordinary atoms. It varies with the kind of matter, but even for the lightest atoms (hydrogen) the charge per unit mass, written e/m, was more than 1,000 times too small. Either each cathode ray had a charge 1,000 times the unit, or a cathode ray is more than 1,000 times lighter than the lightest chemical atom. But all the cathode rays had the same e/m, no matter what the gas or what the metal used for the cathode from which they came. Since in Faraday's experiments the charges seldom exceed 3 units, a constant value of more than 1,000 seemed most improbable, so the particles of cathode rays must have a sub-atomic mass which is the same whatever material they came from.

In the next two years, 'J. J.' brilliantly completed the proof and added new evidence of the universality of what he, not wishing to prejudge the issue of their identity with the unit charge, called 'corpuscles'. He found he could get them from hot wires, and from metals exposed to ultra-violet light. In all cases e/m was the same as for cathode rays within a reasonable experimental error, whatever the nature of the wire or metal. Moreover, he adapted a clever method, just discovered in the Cavendish by C. T. R. Wilson, of making small charges visible by collecting drops upon them, to measure the charge of the 'corpuscles' in the ultra-violet light experiment. It came out within the range expected for the Faraday unit; and though this was wide, it was clear enough that he was not dealing with something more than 1,000 times as large. Hence the corpuscle was at least 1,000 times lighter than the lightest atom. It was established as a universal constituent of all matter; not the only one obviously, since ordinary matter is electrically neutral and 'J. J.'s' corpuscles were charged, but a true universal entity, more nearly recalling the philosophies of the Greeks than nineteenth-century chemistry. In the very paper which described the now classic e/m experiment on cathode rays 'J. J.' turned to the next stage. Granted that electrons are universal constituents of matter, how do they fit in? Lenard's experimental result that the distance a cathode ray could go through matter was inversely as the density over a wide range and independent of its chemical nature or physical state, seemed to 'J. J.' to give strong support for the view that atoms contained electrons in number proportional to the mass of the atom. He considered, correctly, that the collisions of the rays in going through an atom would be rather with the individual constituent electrons than with the atom as a whole, so Lenard's relation implied that the number of electrons per gram is the same for all substances. Ever on the look-out for a model, he adopted an experiment of the American physicist Mayer, which seemed to him to suggest very strongly something like the periodic table.

Now if this has any validity, even in an order-of-magnitude fashion, there will not be many thousands of electrons in an atom, probably only a few. Therefore, the main mass of atoms cannot be due to electrons; presumably it is supplied by the positively electrified component.

Both these questions had to wait while knowledge accumulated on the behaviour of electricity in gases, on the action of X-rays, and on the behaviour of radioactivity, of which Rutherford made himself the master, using, in each case, the electron as a master key.

Much of this work was done at the Cavendish Laboratory. Here the first research school of the modern kind ever to operate in Britain was working all out. Seeing that it started with Rutherford and Townsend as the first two research students, soon to be joined by C. T. R. Wilson, Langevin, Barkla and many others, this is not surprising.

It was, I suppose, the happiest period of 'J. J.'s' life, for though he was an intense individualist in his own work, he enjoyed the companionship of other workers. His own enthusiasm stimulated them as much as his curious insight helped to exorcise the devils that inhabit physical apparatus. He got back enthusiasm in return, the enthusiasm which he so valued as the supreme quality of a good physicist.

In 1906 he was able to make an estimate of the number of electrons in an atom—corpuscles as he still called them. It was a theoretical paper based on the experimental work of Barkla and Rutherford, and using his own formulæ for the scattering of electromagnetic waves by charged particles, that is, X-rays by electrons, and of fast electrons by resting ones. Three methods, the scattering of X-rays, the penetration of β-rays through matter, and less accurately the refractive index of gases, all led to the conclusion that the number of electrons in an atom is of the same order as the chemical atomic weight.

But what then of the positives, which must therefore somehow contribute the lion's share of the mass of all atoms ? 'J. J.' supposed that the atom was like a gooseberry with corpuscles as the pips and the neutralizing positive charge spread out continuously rather like the edible part of the gooseberry. It was left for Rutherford to discover the nucleus. 'J. J.'s' reason for his choice was a rational one in the days when no one questioned Maxwellian electrodynamics. While on the inverse square law a solar system can be stable if the planets *attract* one another, it is inherently unstable—for more than one planet—if they *repel*, as electrons must. The sphere of distributed electricity gets over this objection. The Mayer experiment which gives much the same field as a distributed electric charge only works in two dimensions ; in three dimensions these rings would be unstable, but stability can be restored by making them spin.

A year before, in 1905, 'J. J.' had made his first experiments on positive rays or canalstrahlen. These had been studied by Wien, who had shown that they have values of e/m, and so probably masses, of the order of those of ions in electrolysis. However, Wien's experiment did not allow him to measure e/m with any accuracy, and indeed seemed to indicate that it varied continuously. This was due to bad vacua. By improving the technique, 'J. J.' was able to show that the rays consist of atoms and molecules which have lost electrons in the discharge and been accelerated towards the cathode by the strong electric field in the Crookes' dark space.

The positive rays were thus no new revolutionary particles, but the gaseous ions which the Cavendish had been studying now for a decade. As so often happens when a better technique is applied to something crudely known, the unexpected turned up in the end ; but the first result was to produce for the first time experimental evidence for what everyone had believed for no good reason, namely, that all the atoms of an element had the same mass, and that atomic weight was definite and was not merely a statistical property of large numbers, a mere average. The parabolæ, which appeared on the plates which his assistant Everett, and later Aston, exposed, and which he measured in a little frame sitting perched up on an office stool, each correspond to one value of e/m and so to one mass, the charge being that on an electron, with sign reversed, or a small integral multiple of it.

Some odd things certainly turned up—compounds which disobeyed the laws of valency, triple hydrogen and the like. Then it was found that when neon was in the tube two parabolæ appeared where only one should be. Was the second perhaps a hydride in spite of neon being an inert gas ? There were weighty reasons against, and when the First World War came and stopped work at the Cavendish, both 'J. J.' and Aston believed that the two parabolæ were due to two subspecies of the neon atom, like the isotopes Soddy had found among the radioactive elements. But there was no absolute proof. After the War, as is well known, Aston's pertinacity and experimental skill not only supplied the proof, but also by the greatly improved technique of his mass spectrograph showed that neon, so far from being unusual in having isotopes, was perfectly normal—that indeed its two isotopes were a modest allowance often exceeded by other elements.

'J. J.' always believed that the method of positive-ray analysis had great possibilities for chemists because of the small quantities of material required. It would have pleased him greatly to see its application nowadays to a variety of technical problems.

Though I fear this lecture has been crowded, I have had to omit much. I have only touched on his theoretical work, and said nothing of his suggestion of the 'spotted wave front', which anticipated Einstein's treatment of light quanta, nor of his important work on the electron theory of metallic conduction. Though his experimental work is better known, he started and finished as a theoretician. His fellowship thesis on the relation of dynamics to physics and chemistry helped to clarify ideas on energy. His theory of the recombination of ions is still valid. The "Conduction of Electricity through Gases", for many years a Bible of physics, contains many pieces of his own theory.

His attitude to theory is interesting. Though a first-rate mathematician, he liked something he could visualize or draw in a diagram on the back of an envelope with a halo of equations around it. Hence his life-long attraction to the concrete 'tubes of force' of Faraday and Maxwell, and truly even now there are problems for which these are the most useful picture. The research, so he told me once, that he most enjoyed doing was one on conformal representation in electrostatics. The trouble with experiments, he said, was that you had infinite labour in getting the apparatus to work, and when it did work the experiment was over too quickly. For him the apparatus existed for the experiment, never the experiment to justify the apparatus.

Though he was a man of unusually wide interests and sympathies, physics was his life. He believed that it was bad for a man to do research continuously and that interruptions were sometimes helpful, especially the interruptions of teaching, in sending a man back to his problems with a fresh mind and perhaps with fresh ideas. This made him perhaps more tolerant than he would otherwise have been of his teaching and administrative work, which he took very seriously ; but his strong sense of duty did not always extend to answering letters.

He enjoyed lecturing—but perhaps not preparing lectures—especially in the Royal Institution, and would, I think, have been glad that his centenary is honoured here.

I will conclude with a quotation which expresses his faith in the future of physics :

"A great discovery is not a terminus, but an avenue leading to regions hitherto unknown. We climb to the top of the peak and find that it reveals to us another higher than any we have yet seen, and so it goes on. The additions to our knowledge of physics made in a generation do not get smaller or less fundamental or less revolutionary, as one generation succeeds another. The sum of our knowledge is not like what mathematicians call a convergent series . . . where the study of a few terms may give the general properties of the whole. Physics corresponds rather to the other type of series called divergent, where the terms which are added one after another do not get smaller and smaller, and where the conclusions we draw from the few terms we know, cannot be trusted to be those we should draw if further knowledge were at our disposal."

RECENT WORK ON NUCLEIC ACIDS

AN informal discussion on nucleic acids, held under the auspices of the Colloid and Biophysics Committee of the Faraday Society, was held during October 12 and 13 in Manson House, London (Royal Society of Tropical Medicine and Hygiene). The chair at the opening session was taken by Prof. J. A. V. Butler, who arranged the meeting. At subsequent sessions Sir Alexander Todd, Prof. E. Chargaff and Prof. R. M. Herriott took the chair. Twenty-six papers were presented.

In the first session, Dr. J. Pouyet, J. Hermans and Dr. R. Vendrely discussed preparations of deoxyribonucleic acid of the two categories described by Sadron at the Brussels Congress in 1955. Further preparations of deoxyribonucleic acid from calf thymus have been made which are of the more compact configuration of category 2, and it has been shown that the absorption at 260 mμ is lower for these preparations than for those of category 1. Experiments suggest that the treatment of the nucleoprotein by salt and alcohol may affect the size and configuration of the deoxyribonucleic acid prepared from it. In a later paper, Dr. R. A. Welsh showed that if nuclei from calf thymus are extracted with 0·14 *M* sodium chloride, the deoxyribonucleoprotein can be dissolved in molar sodium chloride and precipitated in a non-fibrous form, in contrast to the fibrous precipitate which is obtained if the nuclei are extracted in water. To some extent the structural changes involved can be reversed, and a fibrous form can be prepared from the non-fibrous nucleoprotein. A further problem in the preparation of deoxyribonucleic acid from calf thymus was raised by Dr. K. V. Shooter, who showed that the small amounts of residual protein (less than 1 per cent) usually found in preparations may markedly influence the physical properties. Treatment with chymotrypsin suggested that 26 per cent by weight of the deoxyribonucleic acid may be cross-linked by the residual protein. A method of preparing deoxyribonucleic acid, involving the partition of a tissue homogenate between phenol and water in the presence of sodium chloride and the chelating agent *p*-amino-salicylic acid, was described by Dr. K. S. Kirby. Using this method, a high yield of deoxyribonucleic acid free from protein has been produced. The various techniques available for the isolation of deoxyribonucleic acid from the bacteriophage D_4 of *Salmonella enteritides* were discussed by Dr. R. Wahl, Dr. M. Joly and Dr. E. Barbu. Viscosity measurements in salt solutions showed that the reduced viscosity of the deoxyribonucleic acid from this phage decreases as the solution is diluted and increases if the solution is concentrated again. To account for these results, it was suggested that the particles consist of short rods (400 A.) associated parallel to each other to form much longer aggregates, the number of rods in each aggregate being dependent on the concentration.

A paper on the properties of deoxyribonucleic acid prepared from the leucocytes of patients with lymphatic or myeloid leukæmia was read by Dr. E. E. Polli. Extensive investigations have shown that many of the physical properties of these preparations are similar to those of deoxyribonucleic acid from calf thymus but that the deoxyribonucleic acid from the leucocytes of myeloid leukæmia has an extra band in the infra-red spectrum and also shows some differences in behaviour on titration to acid *p*H. In addition, the deoxyribonucleoprotein from the myeloid leukæmia leucocytes was found to be 95 per cent dissociated in salt concentrations of 0·4–0·6 *M*, in contrast to the behaviour of calf thymus nucleoprotein and nucleoprotein from lymphatic leukæmia leucocytes which are only 5 per cent dissociated at these salt concentrations.

Further work on the physical properties of calf thymus deoxyribonucleic acid was reported by Prof. P. Doty. The examination of a series of samples of molecular weights from 8×10^6 to 3×10^5, produced by sonic degradation, has shown that $[\eta] \propto M^{1{\cdot}08}$ and $S_0 \propto M^{0{\cdot}37}$. Heat-denaturation studies in the presence of salt have shown that on the addition of hydrogen-bond-breaking agents such as urea or guanidine hydrochloride, the temperature at which a marked fall in viscosity occurs is reduced. The increase in the absorption at 260 mμ increases by as much as 32 per cent if the measurements are made at the temperature of the heating experiments; but on cooling the solution, the absorption falls to only 14 per cent greater than before heating. This change was attributed to the random formation of hydrogen bonds when the solution was cooled. It was also found that the denaturation process is not a first-order reaction, since not only does the rate of denaturation increase with temperature (above the denaturation temperature) but also the extent of the reaction increases. The correspondence between this process and the progressive melting of crystallites in a polymer was discussed. Dr. P. Alexander and Dr. K. A. Stacey dealt with the denaturation of herring sperm deoxyribonucleic acid by urea. At concentrations less than 0·003 per cent, the molecular weight is reduced by about one-half. Electron microscope photographs showing the disappearance of fibrils after treatment with urea at room temperature lend support to their suggestion that the twin strands of the helix are separated under these conditions. The effect of denaturation has been studied by Dr. A. R. Peacocke using titration techniques. These experiments showed that heating or sonic degradation disrupts the hydrogen bonds between the two pairs of bases at random, whereas degradation by γ-rays or by acid treatment produces a non-random rupture of the hydrogen bonds.

Further work on the analysis of the structure of deoxyribonucleic acid and nucleoprotein was described by Dr. M. F. H. Wilkins. Another contribution was made by Dr. H. Wyckoff, who showed that the reversible change from the *A*- to the *B*-form can be produced by varying the alcohol concentration of a solution between 75 and 90 per cent, and that in 90 per cent alcohol the *B*-form can be obtained from the *A*-form by stretching the filaments. X-ray diffraction studies on the synthetic ribonucleotides, polyadenylic and polyuridylic acid, were described by Dr. A. Rich, who showed that on mixing solutions of these two polymers the molecules combine to give a twin-stranded helix. Further work on ribonucleic acid was reported by Dr. R. Franklin, who has compared the X-ray diffraction pattern of tobacco mosaic virus with that from the reconstituted protein. The results show that the ribonucleic acid of the virus lies 40 A. from the axis.

Dr. G. D. Hunter showed that the nucleic acids of *B. megaterium* can be obtained by treatment of the protoplasts with dodecyl sulphate and the ribo- and deoxyribo-nucleic acids separated by sedimentation. Some nucleic acid, mainly deoxyribonucleic acid, which is precipitated with the protein during treatment with the detergent, has been isolated by treatment with chloroform. This deoxyribonucleic acid differs in composition from that which dissolves on treatment with the detergent. Ribonucleic acid from a strain of the organism trained to grow on lactose has the power to induce β-galactosidase activity in an untrained strain in the absence of any other inducer. Dr. A. S. Jones and Dr. A. R. Peacocke reported the isolation of ribonucleic acid from *Aerobacter aerogenes* using sodium cholate as an enzyme inhibitor. Titration studies have shown significant differences between the forward and back titration curves in the acid and alkaline regions. This hysteresis implies the existence of hydrogen bonds on both the 6-amino and the 6-keto groups. Investigations of the composition of the ribonucleic acid in nucleoprotein preparations from a wide variety of organisms were described by Prof. E. Chargaff. In all cases the number of 6-amino groups has been found to be equal to the number of 6-keto groups to within a few per cent, although the ratio of purines to pyrimidines is in general significantly different from unity. Work on the proteins of the nucleoprotein complex was also reported.

New methods of fractionating deoxyribonucleic acid in nucleoprotein using polysulphates were described by Dr. M. Hickens, Dr. P. W. Kent and Dr. P. V. F. Ward. Dr. G. A. Gilbert commented on the use of electrophoresis measurements for studying the interaction between deoxyribonucleic acid and proteins, and showed how it is possible to obtain three peaks in the ascending boundary with these systems. The interaction of herring sperm deoxyribonucleic acid with amino-acids and peptides has been studied by Dr. R. Zahn, who has found that the reaction occurs in two stages: a relatively rapid reaction leading to an increase in solubility in alcohol, followed by a slower reaction in which the solubility is reduced.

Papers on the protein components of deoxyribonucleoproteins were read by Dr. P. F. Davison and Prof. K. Felix. Prof. Felix dealt with the fractionation of the protamines of herring sperm and reported results on the composition and molecular weight of the fractions. Further work on the composition of nucleoprotein of the testes of *Trutta fontinalis* at different stages of maturity has shown that nucleoprotamine appears about the mid-point of the ripening period and that its composition does not change after this stage. At all stages a second basic protein, probably a histone, is also present. These results suggest that the protamine is synthesized by a special process similar to that by which the proteohormones of the glands are formed. Dr. Davison discussed the histones obtained from nucleoprotein of ascites tumour cells. Of these preparations, 25 per cent or less is precipitated at *p*H 6·5; the properties of the remainder are found to be similar to those of histones from normal tissues. Fractionation and analysis of the material precipitated at *p*H 6·5 suggests that it is an aggregate formed from histones and a non-basic protein. There is some doubt whether this non-basic protein is a constituent of the nucleus. Photographs of the isolated nuclei show the presence of cytoplasmic contamination.

Recent work on the transforming principle of *Haemophilus influenzae* was reported by Prof. R. M. Herriott. Sedimentation and diffusion studies have given a preliminary molecular weight of 15×10^6. Investigation of the absorption mechanism using tracer techniques has shown that some of the absorbed deoxyribonucleic acid can be removed by washing or by the action of deoxyribonuclease. For every 1,000 molecules of deoxyribonucleic acid which are irreversibly absorbed, about eight cells are transformed. There is no evidence that the absorption process fractionates the transforming activity. Studies on *Haemophilus* inactivated by ultra-violet irradiation show no reactivation on exposure to visible light. If, however, a cell-free extract of *E. coli B* is added, 30–50 per cent of the original activity of the *Haemophilus* is restored.

Incorporation studies in *in vitro* systems were discussed by Mme. Y. Khouvine and by Prof. J. N. Davidson and Dr. R. Y. Thomson. Mme. Khouvine has investigated the incorporation of phosphorus-32 into the nucleic acids of cell fractions of an epithelioma of the rat under a variety of conditions, and has adduced evidence that the enzyme systems involved in the incorporation differ among the various cell fractions. Preferential incorporation into ribonucleic acid rather than deoxyribonucleic acid is found. Prof. Davidson demonstrated that the incorporation of carbon-14 formate into the nucleic acids of bone-marrow and ascites cells and a strain of mouse sarcoma cells growing *in vitro* occurs to a much greater extent into thymine than into the purines, suggesting that the nucleic acids are synthesized from preformed purines. The addition of a particle-free extract of mouse or pigeon liver results in an increase in the incorporation of carbon-14 formate into the purines, presumably by providing the enzyme system for purine synthesis. Studies on the incorporation of phosphorus-32 into the ribonucleic acid of rat liver were described by Dr. H. N. Munro. The incorporation is considerably lower in rats fasted overnight after a diet containing adequate protein than in rats maintained on protein-free diet. It was suggested that breakdown of ribonucleic acid occurs when the supply of amino-acids is stopped, and that the products dilute the isotopically labelled precursor pool. Feeding protein at the time of injection increases the uptake to that of the rats fed on the protein-free diet.

Investigations made by Dr. D. B. Dunn of the incorporation of some thymine analogues into the nucleic acids of a strain of *B. coli* suggest that there are possibly two routes for the incorporation into deoxyribonucleic acid. The growth inhibition of these analogues is ascribed to the formation of deoxyribonucleic acid in which many breaks occur in one strand of the helix, thus blocking further duplication. Further metabolism studies involving 8-azaguanine were reported by Dr. H. G. Mandel and Dr. R. Markham. The incorporation of the analogue into the ribonucleic acid of *Bacillus cereus* was demonstrated. Addition of guanylic acid to a culture inhibited by the analogue leads to an increase in growth-rate, the analogue being ejected from the bacterial cells as the nucleoside. K. V. Shooter

HYDRAULICS RESEARCH IN GREAT BRITAIN

WORK OF THE HYDRAULICS RESEARCH ORGANIZATION

By F. H. ALLEN
Assistant Director

THE Hydraulics Research Organization of the Department of Scientific and Industrial Research was brought into being in 1947 in order to undertake research into open-channel flow, and, in particular, into the manifold problems of loose-boundary hydraulics as these are met in rivers, estuaries and coastal waters. Since that time, the Organization has expanded steadily until it now has a staff of about 130 and occupies a 90-acre site at Howbery Park, near Wallingford, Berkshire. The director of the Hydraulics Research Station is Sir Claude Inglis, formerly director of the Indian Waterways Experimental Station at Poona. The Station resembles the other research establishments of the Department of Scientific and Industrial Research in that its programme is controlled by a board of eminent engineers and scientists serving in an honorary capacity.

During 1947–51 the new Organization worked in cramped and temporary quarters at the National Physical Laboratory, while the new research station was planned and constructed at Wallingford. The Organization was transferred to Wallingford from 1951 and has been operating there in full strength since the summer of 1952. The nineteenth-century Manor House of Howbery Park has been converted for use as offices, and also includes the library, drawing office and canteen. In the first years at Wallingford, much of the work was carried out on the open-air research facilities, which were available long before the main covered accommodation which is now the nucleus of the Station. These open-air facilities include two large wave basins, each measuring 80 ft. by 125 ft. and equipped with permanent wave-generating machinery, and a pair of unusually long experimental flumes or channels of rectangular cross-section, one 5 ft. and the other 12 ft. in width and both approximately 350 ft. in length. The wave basins are used for model investigations of harbours and for loose-boundary studies of the formation, development and protection of beaches. The channels are devoted to basic research into factors affecting the regime shapes and slopes of alluvial channels. For some time from 1952 it was also necessary to make use of existing temporary accommodation in the form of small precast concrete sheds. A valuable wave tank, 10 ft. wide and 54 ft. long, was constructed in one of these buildings and has since been used for a variety of investigations, including studies of the stability of various breakwater sections and experiments to determine how the rate at which water particles drift in the presence of waves varies with depth. Certain small models and experimental flumes were also built in temporary sheds at this period.

The major part of the permanent experimental accommodation of the Station became available for use only in January 1955. The Main Hall as it now stands measures 300 ft. by 200 ft., and the interior is unobstructed except for two columns supporting the roof. The ceiling is about 25 ft. above floor-level. This impressive building is known as Stage 1 of the Main Hall, and major extensions to it are planned for erection in further stages during the next decade, the overall length of the final structure being 700 ft. The Main Hall has a radiant heating system and ample supplies of water, electrical power and artificial light; it has provision for water storage and drainage below floor-level and photographic facilities at ceiling-level. Transporter gantries are also suspended from rails at ceiling height. The floor consists of consolidated earth, loosely stabilized with a cold bitumastic emulsion, and may be excavated as required for the construction of hydraulic models. As accommodation for hydraulic research, the building has won the admiration of many home and overseas visitors, and the facilities it provides in this respect are undoubtedly second to none in quality and flexibility. Attached to the Main Hall is a subsidiary block in which the various workshops and smaller general-purpose laboratories (for mechanization, development of instruments, analysis of sediments and photographic processing) are housed.

In addition to basic or background research on open-channel flow and wave action, the Station carries out a considerable amount of *ad hoc* or applied research—indeed, at the present time, about three-quarters of the total effort of the establishment is devoted to applied research on specific problems of one kind or another. Typical objectives of these investigations are the dissipation of turbulence below falls, sluices and similar hydraulic structures, the prevention or reduction of flooding, the improvement of shipping channels in ports and estuaries by the control or reduction of siltation, the damping of waves entering harbour and river mouths, and the control or retardation of coast erosion by wave action and tidal currents. These studies are carried out—usually on a repayment basis—on behalf of government departments, river boards, port authorities, coastal protection and local authorities, consulting engineers and private individuals. Work is also carried out for overseas members of the Commonwealth and for certain foreign countries.

The laws of similitude as applied to hydraulic models are sufficiently well known to need no detailed exposition. It is sufficient to say that, as gravitational forces predominate in most of the problems with which the Station is concerned, the Froude law is of over-riding importance in experimental work with scale models. In the study of problems involving the scour, transport and deposition of channel-bed material, movable-bed models—moulded in sand, pumice or some such incoherent granular substance—are used. The limitations of similitude in such models are recognized, and have indeed been the subject of controversy; but it is now well established that they are invaluable aids in the solution of complex problems of bed movement and siltation. The similitude which can be demonstrated to exist in movable-bed models has not yet been fully defined by a mathematical analysis, and experimental work on models of this type can therefore be described with some justice as being partly an art and partly a science. Certainly it is a field of work where wide experience is essential, and where results must be subjected to continual scrutiny and comparison with the known behaviour of the natural prototypes.

The concept of regime, first developed on an empirical basis from a study of canals in India, has been found to be of wide application in the field of loose-boundary hydraulics and is itself the subject of basic research at the Station. In its application to uni-directional flow in alluvial channels—an aspect of the subject which is receiving an increasing amount of attention in the United States—regime theory relates the width and depth of a channel to the water discharge, the slope of the water surface and the quantity and nature of material in movement on the bed and in suspension. The application of this theory to hydraulic models is in itself an obvious subject for research.

There would be little point in listing all the investigations now in progress at Wallingford, but some idea of the scope of the research programme may be given if a few of the major projects are singled out for mention. Thus in the realm of tidal flow in estuaries, two major investigations of siltation are in progress—one concerning the deterioration of the upper estuary of the Mersey, and the other being aimed at the stabilization and deepening of the shipping channel at and below the port of Chittagong on the Karnafuli River in East Pakistan. A tidal study of a different type is in progress in a rigid-bed model of the tidal Trent, where methods of protection against combinations of river and tidal flooding are being tested. A large proportion of the Station's effort is devoted to studies of wave action. In one of the wave basins a large model of the proposed design for the new harbour to be built at Tema, on the Gold Coast, is being examined to determine its behaviour under the influence of short-period and long-period waves. A model of a new sea wall for the Lincolnshire bank of the outer Humber is being subjected to two-dimensional tests in the 54-ft. wave tank. The formation of a sand-bar across the entrance to Eyemouth Harbour in Berwickshire is being studied in a 1/40-scale model equipped with pneumatic wave generators. Investigations of river problems and hydraulic structures also figure largely in the Station's programme of applied research and experimentation. In conclusion, mention should be made of radioactive isotopes as tracers for indicating the movements of silt and sand, in the use of which the Hydraulics Research Station, in collaboration with the Atomic Energy Research Establishment at Harwell, has carried out valuable pioneering work.

OBITUARIES

Mr. John Evershed, C.I.E., F.R.S.

By the death on November 17 at the age of ninety-two of John Evershed, we have lost the *doyen* of British astronomers. Born on February 26, 1864, at Gomshall in Surrey, he was educated privately and started to work in the chemical industry. He early developed an interest in astronomy and established his own observatory at Kenley in Surrey in 1890. In that year he became one of the founder members of the British Astronomical Association and director of the Section of Solar Spectroscopy. With a small telescope and a spectroscope of his own design and construction, and later with a spectroheliograph also built by himself, he recorded 11,000 solar prominences during his sixteen years work at Kenley. The Evershed solar spectroscope is still an instrument in use to-day.

In 1906 he was appointed assistant director of the Kodaikanal Observatory; in 1911 he succeeded Michie Smith as director, retiring to England in 1923, when he was created C.I.E. in recognition of his work in India. At Kodaikanal he continued his work on prominences and with Mrs. Evershed he published an important memoir on the distribution of prominences during the course of a solar cycle: they noted the excess of eastern over western prominences, the longward displacement of the lines in their spectra and the link between sunspots and metallic prominences. Evershed also greatly improved the quality of the spectroheliograms obtained at the Observatory. His work on sunspot spectra led to his best-known discovery, the radial motion of gases, outwards across the penumbra of a sunspot and inwards at higher levels in the solar atmosphere. This work, published in 1909, led to his election to the Royal Society in 1915 and to the award of the Gold Medal of the Royal Astronomical Society in 1918.

Other work carried out by Evershed at Kodaikanal included studies of solar rotation, of the spectra of comets, Venus and Nova Aquilæ 1918, of the displacement of lines to the red at the centre and limb of the Sun. He also chose a site for the Cawthron Observatory in New Zealand and travelled to the Vale of Kashmir to find a site with first-class seeing for a solar observatory in India. He observed eclipses in Norway, 1896; India, 1898; Algeria, 1900; Spain, 1905; Australia, 1922; and Yorkshire, 1927. Among his eclipse results were the first record of the chromospheric continuous spectrum at the head of the Balmer series and his successful securing of long exposures on the chromosphere by stationing himself close to the edge of the belt of totality.

On his return from India, Evershed settled at Ewhurst in Surrey, where he built himself an observatory for solar work, continuing to obtain high-class spectroheliograms and high-dispersion solar spectra. His chief point of interest lay in exact wave-lengths of lines in the spectra of prominences and of the centre and limb of the solar disk. In a series of papers, giving measures of the highest degree of accuracy and continuing until the year 1949, he discussed the varying displacements of lines to the red. He reached the final conclusion that the Einstein gravitational effect was the main cause of the displacements, though the result was modified by Doppler and Lindholm effects. He also examined some Mount Wilson plates that had been used to determine the general magnetic field of the Sun and concluded that the observed slight displacements were due to localized Doppler effects.

The last published report of the work of his observatory was for the year 1950. On closing it down finally, he presented some of his instruments to the Royal Greenwich Observatory at Herstmonceux.

Evershed married in 1906 Miss Mary Acworth, and she collaborated actively with him in his researches until her death in 1949. He was married a second time in 1950, to Miss Margaret Randall, who survives him.

F. J. M. STRATTON

Dr. A. J. Carlson

WHEN he died on September 2, Dr. Anton Julius Carlson bore the illustrious title of "Frank P. Hixon distinguished service professor emeritus of physiology, University of Chicago".

Carlson was born in Sweden in 1875 and went to the United States in 1891. He graduated A.B. at Augustana College, Rock Island, Illinois, in 1898, A.M. the following year, and Ph.D. in physiology at Stanford University in 1903. After spending one year as a research associate at the Carnegie Institution, he joined the Department of Physiology of the University of Chicago in 1904 and remained there until he retired in 1940 from the positions of professor and chairman of the Department. As professor emeritus he continued actively at work, and himself told a Committee of the House of Representatives in 1950 that "for the last ten years I have been emeritus or demeritus, whatever you call it; however, the only thing I retired from ten years ago was my salary". In the U.S. Army during 1917–19 he was a lieutenant-colonel in the Sanitary Corps, and while serving in Sweden was given the honorary degree of M.D. by Lund. He held honorary degrees from seven universities.

Carlson's early work was on the rate of conduction of impulses in nerves and, after some excursions into the comparative physiology of the circulation, he did his main work upon the physiology of the alimentary tract and of the visceral sensory nervous system. Apart from some two hundred papers, he wrote two books: "Control of Hunger in Health and Disease" and "The Machinery of the Body".

Carlson was honoured by many institutions. He was elected to the U.S. National Academy of Sciences in 1918, to the American Physiological Society in 1904 (being secretary during 1910–14 and president 1923–25), and to a variety of others in the United States and abroad. He had also served as president of the American Association for the Advancement of Science, the American Biological Society, the Federation of American Societies for Experimental Biology, the Institute of Medicine, the American Association of University Professors, and the National Society for Medical Research. In 1935 he lectured in China under the auspices of the Rockefeller Foundation, and he was a frequent traveller, attending seven international physiological congresses between 1909 and 1950, and the international gerontological congress in London last year.

Carlson was a great teacher, and himself said that he had taught between 8,000 and 10,000 medical students, and 75,000–100,000 other students. He was forthright, very outspoken and a keen controversialist. His work as a consultant on Government organizations (such as the Food and Drug Administration and the Office of Scientific Research and Development) often enlivened meetings; but surprising though his statements sometimes appeared, they were always backed by experimental facts, often elicited in his own laboratory.

H. M. SINCLAIR

NEWS and VIEWS

Hungary: American Scientists' Resolutions

THE U.S. National Academy of Sciences at its autumn meeting in Washington adopted the following resolution respecting recent events in Hungary: "Those members of the National Academy of Sciences of the United States of America present at a meeting in Washington on November 10, 1956, unite in expressing their profound admiration and sympathy to fellow scientists in Hungary and to all the men and women of that nation who have demonstrated their love of liberty with sacrificial devotion during the tragic events of the past few weeks. American scientists look forward with hope to a time when their Hungarian colleagues, freed from external oppression, will be able to join fully in the international exchange of information, discussion and encouragement which is essential to the progress of science". Dr. Detlev W. Bronk, president of the Academy, expressed his satisfaction that the Academy's resolution could be associated with a similar statement adopted by the American Philosophical Society. "It is appropriate," he said, "that the Academy should join with the American Philosophical Society, the oldest of the great scholarly societies of the United States, in a matter so closely related to the unconquerable yearning of mankind freely and courageously to advance its highest human and cultural ideals. The statements of the Academy and of the Society recognize with humility and deep gratitude the desperate and courageous struggle of Hungarians for those principles which are precious to all who value the right to seek truth and to teach it freely."

Institute of Metals: Awards

THE Institute of Metals have made the following awards: *Institute of Metals (Platinum) Medal for* 1957: Dr. Maurice Cook, joint managing director, Imperial Chemical Industries, Ltd., Metals Division, in recognition of his outstanding contribution to the science of metallurgy, to the non-ferrous metals industry and to the welfare of the metallurgical profession; *Rosenhain Medal for* 1957: Dr. H. K. Hardy, research manager, United Kingdom Atomic Energy Authority, Industrial Group, in recognition of his outstanding contributions to knowledge in the field of physical metallurgy.

University of Leeds Appeal

IMMEDIATELY before the War the number of full-time students at the University of Leeds was about 1,750. The number has now increased to 3,700 and, among these, the number reading science or technology has grown from 560 to 1,700. In five or six years time it is expected that there will be 5,300 students in all, of whom 3,000 will be reading science or technology. During the past sixteen years the research work of the University has developed at a rapid rate and will develop even more quickly in the next five or six years. To meet these demands, the

University has embarked on a building programme which must be completed in the next five or six years and will cost, in all, about £6,000,000. Most of this money will almost certainly come from the Government which, on the advice of the University Grants Committee, has selected Leeds as one of four universities outside London for 'major developments' in the field of scientific and technological education. The Government has made it clear, however, that it has chosen to help the University of Leeds largely because it believes that Leeds can continue to count on help from other sources; for at least £600,000 of the total needs the University has to look to industry and commerce and to private benefactors. Already £200,000 of this sum has been assured by gifts and promises. The Vice-Chancellor has now issued an appeal to many firms to help the University in its development work. There is little doubt that the appeal will be successful.

Rotherham College of Technology

To mark the twenty-fifth anniversary of the opening of the main building of the Rotherham College of Technology, a Jubilee Foundation Lecture was delivered on November 6 by Mr. R. F. Jackson, operations group leader in the Reactor Division of the Atomic Energy Research Establishment at Harwell, on "Research Reactors in the Nuclear Power Programme". During the quarter of a century since its foundation the Rotherham College of Technology has made a valuable contribution to industry in the Rotherham and Sheffield area. In carrying out extensive pioneer work in technical education it has established a high reputation, both locally and nationally; and during the past four years it has become the regional centre for south Yorkshire for powder metallurgy, furnace brickwork and for sandwich courses in mechanical and electrical engineering.

Clinica Chimica Acta

The newer biochemical techniques, in particular improved methods of separation, such as chromatography and electrophoresis, and the use of isotopic tracers, are opening endless avenues for exploration by those engaged in medical research. As a result, papers on clinical biochemistry are appearing in ever-increasing numbers. These papers are now spread among a wide variety of journals and are often regarded as too clinical by the pure biochemist and as too biochemical by the pure clinician. As a result, in several countries journals have been, or are being, initiated to cater for clinical biochemistry as a scientific discipline in its own right. Messrs. Elsevier have given substance to hopes expressed at the first International Congress on Clinical Chemistry, held in Amsterdam in September 1954, that there should be started an international journal in this field. The new journal is a commercial venture, not attached to any scientific society, and the publishers have been able to assemble an editorial board and an advisory board impressive in their high standing, and carrying assurance of a sound editorial policy (Elsevier Publishing Co., Ltd., Amsterdam, London, Houston, New York. Six issues per year, of approximately 100 pages each. £4 10*s*. per volume of 6 issues). The international flavour is shown both by the composition of the editorial board (the fourteen members of which represent eleven countries) and by the authorship of the thirty-one papers in the first three issues, contributed from ten countries. A very desirable, but probably rather expensive, feature is that summaries of all papers are given in four languages—English, French, German and Russian. This should encourage one of the subsidiary hopes of its founders, namely, that the journal will promote some degree of standardization in biochemical procedures applied to medicine, and thereby facilitate mutual interpretation of results. The format and standard of production are of the high quality which one has learnt to associate with Elsevier publications. The price, as seems almost inevitable nowadays, makes the journal more likely to be taken by libraries than by individuals. If a high editorial standard is maintained, this journal is likely to come to be considered of prime importance in all institutions concerned with clinical biochemistry.

Midwest Research Institute, Kansas City: Annual Report

The annual report of the Midwest Research Institute, Kansas City, Mo. (pp. 16; 1956), presented by the president, Dr. C. N. Kimball, to the Trustees at their eleventh annual meeting on May 14, records a 20 per cent increase in the amount of contract research, which amounted to 2,170,000 dollars in value on 503 different projects for 208 sponsors. Of the Institute's full-time staff, 175 are professional research workers and more than half the work was based on ideas originating with the Institute's own staff. Among projects noted by Dr. Kimball are the work on air pollution in Los Angeles, now in its third year, involving the determination of the effect of materials emanating from automobile exhausts; the development of industrial products, such as polymers from non-edible tallows and greases; and the design of an electromechanical device which, in a relatively small space, simulates operating conditions in an oil-well with respect to the performance of its components. In the field of automation, methods and equipment have been developed for checking practical horse-power motors to meet the requirements of the National Electrical Manufacturers Association, and among the projects on which the eleven people engaged in marketing research have been occupied is an analysis of factors affecting the market potential for anhydrous ammonia as fertilizer. Those engaged in operations research have made a study of the possibility of setting up a mathematical model which would govern inventory policy. Work has been done on the addition of chemicals to food prior to irradiation, and a group of people with extensive experience in the field of nuclear energy is being formed. Projects bearing directly on public health or wealth included broad studies of the basic economy of the Great Plains Area; methods of transmitting to the mind of the blind person information about objects beyond his reach; and the development of an artificial lung and heart to permit operations on the human heart itself. Dr. Kimball believes that in future the production of new technology will become a competitive business activity, and he also stresses the importance of new materials and techniques.

Pacific Science Board: Report for 1954

The eighth annual report of the Pacific Science Board for 1954 (pp. 61. Washington, D.C.: National Academy of Sciences—National Research Council, 1955) summarizes the progress made in studying the environmental factors affecting life on coral atolls, which has been the chief activity of the programme of the scientific investigations in Micronesia. Vegetation and soil distribution and character for thirty-three islets at Kapingamarangi in the Southern Carolines were plotted by the geographer and land ecologist, and the general ecological relations between climate, vegetation, soil character, current and wave effects were plotted on the maps as "land use formulæ" for later analyses. The total fish fauna was intensively studied, as well as the present and potential fisheries. The programme also seeks to develop criteria for estimating the carrying capacity of an atoll. The Invertebrate Consultants Committee for the Pacific continued its investigation as to whether *Gonaxis kibweziensis* snails effectively control the *Achatina fulica* snails on the island of Agiguan, and completed work on the identification of various scientific collections of importance to the ecological study of Pacific atolls. Scientific investigations in the Ryukyu Islands was limited to the preparation of reports and the completion of the nine-month study of cultural changes in Okinawa resulting from the United States military occupation. E. H. Walker's report on important trees of the Ryukyu Islands was published by the Civil Administration of the Islands. Approved field projects included studies of social and economic life in the Society Islands; of law in a primitive society in the Netherlands New Guinea; of mosquitoes in the South Pacific area; and a preliminary study of social aspects of depopulation among the Murits of British North Borneo. Among the matters discussed by the Conservation Committee for Micronesia were the extension of the season for collecting the shells of *Trochus niloticus*, the proposed Palau reserve, forestry practice in the Trust Territory, the introduction of bamboo and implications of the possible release of carrion crows and land snails on islands other than Agiguan. Details are given of Fulbright awards during 1954–55 for research or lecturing in Pacific and East Asian countries.

An Expedition to Papua

A SUMMARY of the results obtained by the fourth Archbold Expedition to New Guinea (1953)—in fact to E. Papua and adjacent islands—under the editorship of L. J. Brass has now appeared as a bulletin of the American Museum of Natural History (3, 2, 83–152; 1956). The summary report gives brief accounts of the physiography, geology and climate of the regions surveyed, together with notes on the economy of the native peoples, previous expeditions and collections and major plant communities. In conformity with previous expeditions of the Archbold series, the main purpose was the collection of biological materials and ecological and distributional studies of mammals, reptiles, amphibians, freshwater fishes, insects, spiders and plants. As the avian fauna of the region was considered to be fairly well known, less attention was given to the collection of birds. Ectoparasites of mammals and soils for screening for antibiotic-producing micro-organisms were also collected. In terms of these materials, the results of the expedition included the following collections: mammals, 1,954; birds, 91; reptiles and amphibians, 1,645; freshwater fishes, 145; insects and spiders, 80,000; ectoparasites of mammals, 750; materials for antibiotic research, 126; plants, 3,445; anthropological items, 34.

Macrolithic Culture of Florisbad, South Africa

THE explorations at the fossil springs at Florisbad in the central province of the Union of South Africa will be always associated with the name of the late Prof. T. F. Dreyer, who described the rich archæological material from the site and had the good fortune to discover the Florisbad skull. A paper on the "Macrolithic Culture of Florisbad" (*Res. Nat. Mus., Bloemfontein*, 1, Part 9, 205; 1956) was in the course of preparation by Prof. Dreyer when he died, and we owe its completion to Prof. A. J. D. Meiring. At the site there are four peats, and while the tools in the upper three are mostly made from lydianite, those from Peat I and below are almost entirely fashioned from dolerite. This early industry may well be considered, then, as a distinct culture from those which occur later on. While carbon-14 dating of the peats, frankly, has not been too satisfactory, it is clear that Peat I was laid down a very long time ago, somewhere about 35,000–40,000 years before our era. The industry here described is very coarse and such as one might expect to be made from pieces of dolerite. There are choppers, coarse points and what Meiring describes as pyramids. One or two specimens can perhaps be termed proto-hand axes; but these rough chopping and pounding tools fall into no very definite category of industry. Some of the dolerite tools were found by Prof. Dreyer in close association with the human skull fragments. Florisbad is an interesting and puzzling site. It cannot be said that we yet have enough knowledge of South African prehistory to fit it exactly into the prehistoric story.

Forestry Commission: Report for 1954–55

IN the Forestry Commission's report on forest research for the year ended March 1955 (pp. 140+12 plates. London: H.M.S.O., 1956; 5*s*. 6*d*. net), it is stated in the introduction that changes are taking place owing to the fact that problems of establishing forests are now becoming less prominent while those of maintenance, protection, management and utilization are becoming more important—an experience which every country taking up forestry seriously has been through. As regards research, there still remain several types of land on which research must be prosecuted to obtain an assurance that successful crops will be attainable. An example is the poor *Scirpus* peats of the north and north-west of Scotland. Experiments have achieved success, where the exposure is not too severe, with intensive cultivation; but more research remains to be done, which is being undertaken with the help of the Macaulay Institute of Soil Research, Aberdeen. Another type of land which has received much recent attention is the ground which lies above the Commission's present planting elevation. Here the current problem is to find out whether it is possible to plant higher and at the same time to obtain a satisfactory yield return. There are very considerable areas of this type of land available for possible treatment. A soils section has been formed at Alice Holt Research Station to carry out routine investigations in conjunction with other sections undertaking this type of work. A summary of the year's work is given by M. V. Laurie, who deals with nursery work, pilot plots for afforestation purposes, ecology, genetics, pathology and entomology and grey squirrels, with a very interesting summary of machinery research that shows the remarkable advances made under the direction of the Forestry Commission. The investigations on mycorrhiza which were commenced at Bedford College, London, are being continued. In other respects the report is on the lines of previous ones.

Fixation of Atmospheric Nitrogen by *Hippophaë rhamnoides* L.

G. Bond and J. T. MacDonnell (*Ann. Bot.*, 20, 79, 501; 1956) have shown that when *Hippophae* plants were inoculated at the six-leaf stage with a suspension of crushed nodules, they began to develop nodules in about two weeks and soon afterwards were able to grow satisfactorily in culture solution free of combined nitrogen. Some 79 mgm. nitrogen per plant was accumulated during seven months of active growth. They conclude that the nodules fix atmospheric nitrogen, and that in its nitrogen nutrition the *Hippophaë* plant shows a close similarity to the nodulated legume. They point out that *Hippophaë* and the other angiosperms with nitrogen-fixing root nodules are all woody species or belong to a family which includes woody types. They also make the interesting suggestion that the physiological property under consideration is a very ancient character and may go back to a period when only woody plants existed. In a further study, G. Bond has found that field nodules of alder, like those of plants grown in the greenhouse, regularly fix nitrogen (*New Phytol.*, 55, 2, 147; 1956).

Scintillation of Starlight

A PAPER by A. H. Mikesell on "The Scintillation of Starlight" (Pub. U.S. Naval Obs., Series 2, 17, Part 4, 143; 1955) describes the results of the observations of scintillation since 1950. The two main objects of the investigations were to measure its effects on the accuracy of stellar photometry and to locate the underlying meteorological causes of the phenomena; and a very full description is given in the paper of the equipment, reduction of observations, discussion of the results, etc., with numerous diagrams. It was found that harmonic components of scintillation decreased with frequency approximately uniformly from 0·1 c./s. to about 500 c./s. Many combinations of telescopes and photoelectric photometers were used, and it was found that the form of the optical equipment was unimportant so long as the objective aperture was circular and all incident light reached the photo-tube. Seasonal variations in scintillation plotted against different frequencies gave the largest values at high frequencies. There was a correlation between scintillation and the maximum speed of winds aloft, especially with winds at altitudes of 8–16 km., but at levels much lower than this region the correlation was not so obvious. At frequencies higher than 150 c./s. the action of the wind was most striking, and on thirty-eight nights when scintillation was observed at frequencies greater than 550 c./s. the maximum reported speed aloft was always greater than 85 m.p.h.; on sixty-two other nights when scintillation appeared only at frequencies less than 550 c./s. the maximum wind-speed exceeded 85 m.p.h. fewer than ten times, and the average maximum speed was 72 m.p.h. with a standard deviation of 23 m.p.h. Detailed examination of the distributions of winds or temperatures on each of the hundred nights of observations showed that there was no correlation of scintillation with a common weather characteristic, such as wind shear, wind direction, location of wind maximum or minimum, intermediate temperature inversion, location or minimum value of the stratospheric temperature, or temperature lapse-rate. The variation of scintillation with zenith distance *z* of the light source was found to be sensitive to frequency; while scintillation is constant at about 100 c./s., below or above this frequency it changes greatly with *z*, a fact which encourages the use of Polaris as a scintillation source in routine observations. Although there is some correlation between scintillation and seeing, more extensive observations and more definitive criteria of seeing are necessary before accurate assessment of the correlation can be made.

Smuts Collection of the Transvaal Museum, Pretoria

IN Bulletin No. 2 of the Transvaal Museum, Pretoria, it is stated that the Smuts collection has, with the consent of the Minister of Education, Arts and Science, been deposited by the Union Archives in the Transvaal Museum. The collection comprises a wealth of items belonging to the late J. C. Smuts and include his field-marshal's baton, medals and decorations, numerous freedoms of cities and other presentations, together with many personal items.

Announcements

PROF. W. T. ASTBURY, professor of biomolecular structure, University of Leeds, has been elected a foreign member of the Swedish Royal Academy of Sciences.

DR. D. S. DANE has been appointed lecturer in microbiology in The Queen's University of Belfast.

DR. G. R. HARRISON, dean of science at the Massachusetts Institute of Technology, has been awarded the first Pittsburgh Spectroscopy Award, which has been established by the Spectroscopy Society of Pittsburgh in recognition of distinguished contributions to this field of science. Among Dean Harrison's outstanding achievements are his numerous studies of line spectra, the measurements and compilations for the "M.I.T. Table of Wavelengths" and important contributions to the ruling of gratings; for ten years he has been editor of the *Journal of the Optical Society of America.*

THE Council of the Gesellschaft Deutscher Naturforscher und Ärzte has decided to establish from time to time a competition to direct attention to certain problems, in natural science and medicine, which call for special discussion, and a prize of D.M. 7,000 has been allocated this year for treatises on "The Formation of Stars by Condensation of Diffuse Matter". Entries may be in English, French or German and should be submitted by April 30, 1958, to the Hamburger Sternwarte, Hamburg-Bergedorf, Gojenbergsweg 112, from which further information can be obtained.

THE fifth International Congress of the International Association on Quaternary Research will be inaugurated at Madrid on September 30 and closed at Barcelona on October 3, 1957. Meetings will comprise sessions dealing with a wide range of subjects bearing on Quaternary geological studies. There will be excursions centred on both cities and into the country between them, to study Quaternary geology and Palæolithic sites. Further information can be obtained from Señor L. Solé Sabaris, Instituto Geological, Universidad, Barcelona, Spain.

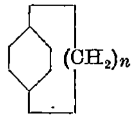
ERRATUM. The title of the communication by Dr. Winifred M. Watkins and Prof. W. T. J. Morgan in *Nature* of December 8, p. 1289, is incorrect; it should read, "Role of O-β-D-Galactopyranosyl-(1 → 4)-*N*-acetyl-D-glucosamine as Inhibitor of the Precipitation of Blood Group Substances by Anti-Type XIV Pneumococcus Serum".

HIGH-RESOLUTION NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY

HIGH-RESOLUTION nuclear magnetic resonance spectroscopy is a rather recent addition to the arsenal of the physical chemist. It has undergone a very rapid development during the past two years, due in large measure to the fact that nuclear-resonance spectrometers with a high degree of field stability are now commercially available. The term 'high-resolution' is generally used for nuclear-resonance measurements of liquid samples under conditions of magnetic-field homogeneity which permit resolution of the signals of non-equivalent nucleii in a given compound and also the fine-structure components arising from spin–spin coupling. The broad resonance signals characteristic of solids, on the other hand, are frequently termed 'broad-line' spectra. There is now ample evidence that the high-resolution nuclear-resonance technique is a very powerful one, and sufficient understanding of the basic phenomena has been gained to demonstrate its advantages as well as some of its limitations.

The basic problem in high-resolution nuclear magnetic resonance work is that of relating the various magnetic effects of the molecule which are measured to the more familiar notions of the chemist regarding electronic structure and molecular configuration. This problem was the central topic of discussion at an informal symposium held during September 6 and 7 at the National Research Council Laboratories in Ottawa. A detailed theoretical treatment of the chemical shift was discussed by Dr. J. A. Pople (Cambridge). The chemical shifts observed can be conveniently discussed in terms of circulating electron currents within the molecule which are induced by the magnetic field. These currents can be classified into three types according to their origin. First, there is the diamagnetic circulation about individual atoms of the molecule corresponding to the well-known Lamb shielding term. This type of magnetic shielding for a given nucleus can frequently be correlated with the electronegativity of neighbouring atoms in the molecule. A second type of circulation may occur in molecules where the nucleus under consideration is bonded to an atom with an electron structure which permits mixing of the ground-state with excited states, so as to give rise to an anisotropic magnetic permeability. It can be shown that this effect will dominate in certain cases where mixing involves transitions between *s*- and *p*-functions or between two *p*-functions. The simple hydrides ammonia, water and hydrogen fluoride are examples of the former, and acetylene of the latter. The chemical shifts of these molecules are anomalous. Dr. W. G. Schneider (Ottawa) reported that the chemical shifts of ammonia, water, hydrogen fluoride and hydrogen chloride, when in the free or unassociated state, lie on the high-field side of the proton signal in saturated hydrocarbons and do not differ markedly from each other. These results cannot be explained on the basis of electronegativity considerations but are readily interpreted in terms of the theory. On association (hydrogen bonding), the proton signals of these hydrides shift to lower field, the shift for hydrogen fluoride being very large, of the order of 8–9 parts per million.

A third type of circulating current is peculiar to aromatic molecules and arises from the circulation of the mobile π-electrons in a magnetic field. As a result, the proton signal of benzene will occur at lower applied field than that of ethylene. The theory provides a rather satisfactory interpretation of the observed chemical shifts of the protons of aromatic hydrocarbons. Further refinements of the theory were discussed by Dr. J. S. Waugh (Massachusetts Institute of Technology), as well as a very interesting experimental confirmation. When a proton is not in the plane of the aromatic ring as in benzene, but out of plane in the vicinity of the hexagonal axis, the chemical shift should be in the opposite direction, that is, to the high-field side of ethylene. This was confirmed by observing the relative proton shifts in compounds of the type:



Several other contributors had also independently observed proton shifts to higher field which can be satisfactorily explained by aromatic ring effects. Dr. A. Bothner-By (Harvard) reported an anomalous shift to high field of the chloroform proton in benzene solution. As a result of complex formation between chloroform and benzene, the chloroform proton signal is modified (shifted to higher field) by the ring current in benzene. This problem was also investigated in greater detail by Dr. L. W. Reeves (Ottawa), who showed that this anomalous shift in chloroform can be observed with benzene, toluene and mesitylene, which complex with chloroform, but not with nitrobenzene or *o*-dichlorobenzene. Dr. J. R. Zimmerman (Magnolia Petroleum Company, Dallas) reported that the proton signal of benzene itself shifts on dilution with hexane; this can be attributed to a preferred mutual orientation of benzene molecules causing a modification of the proton signal by the ring effect. In a dilute solution of benzene this effect will be absent.

The large chemical shifts accompanying hydrogen bonding and association were discussed by several contributors. Dr. C. Reid (University of British Columbia) found that on successive dilution of ethanol with carbon tetrachloride the proton signal of the O—H group, which in pure alcohol is shifted about 5·5 parts per million on the low-field side of the methyl group, moves to high field, until in very dilute solution it appears on the high-field side of the methyl signal. The N—H proton signal in amines shows a similar behaviour. These large shifts of the proton signal accompanying hydrogen bonding are not yet understood. Dr. Zimmerman described a careful and detailed study of alcohol–water solutions. A plot of the chemical shift of the OH proton signal (measured relative to the alcohol methyl signal) against concentration exhibits a discontinuity. Some alcohols give rise to more than one such discontinuity. The correlation time for proton exchange between water and ethanol was found to be of the order of 15 msec. Mr. A. Van Steenbergen (McGill) has studied the chemical shifts accompanying association of a number of alcohols, and the corresponding deuterated alcohols, as a function of temperature, by means of the spin-echo technique.

Nuclear resonance techniques have been very successfully applied by Dr. W. D. Phillips and his associates (Dupont Company, Wilmington, Delaware) to the problem of hindered internal rotation and *cis-trans* isomerism. Fluorine signals in halogenated ethane derivatives as well as proton signals in substituted nitrosamines were found to be double. At higher temperatures these coalesced to a single line. Assignment of the signals to individual isomers could be made. Dr. Phillips also discussed several examples of fluorine exchange in halogen fluorides. The spectrum of ClF_3, for example, which is sharp at − 60° C. but becomes broad at room temperature, can be accounted for by fluorine exchange, involving an activation energy of about 6 kcal.

Dr. P. C. Lauterbur (Mellon Institute, Pittsburgh) has been able to observe for the first time nuclear resonance signals of carbon-13 in natural abundance in a variety of organic and inorganic compounds. The resonances were observed in the dispersion mode at a fixed frequency of 8·5 mc./sec. and a field of about 7,940 gauss. Large variations in the chemical shift were found in the compounds measured, and the spin–spin coupling constant was found to be large (120–270 c./s.). The measurement of carbon nuclear resonances appears to be a very promising future development in the chemical field.

Considerable progress has been made in the problem of understanding and analysing the multiplet structure of high-resolution nuclear magnetic resonance spectra due to spin–spin coupling of the nuclei in a given molecule. The theory of multiplet splitting was outlined by Dr. J. A. Pople, as well as a detailed analysis of the interesting cases which arise when the J-coupling constant is of the same order of magnitude as the chemical shift, δ. Dr. H. J. Bernstein (Ottawa) discussed a number of observed spectra in which these conditions are met and which can be broken down into characteristic spectra of groups of two, three and four interacting nuclei. Analysis of the spectra gave excellent agreement with the theory. Although the meaning of the J-coupling constants in terms of electronic structure is as yet not understood, the values of these constants show significant differences in different classes of compounds.

Chloride ion resonances of chloride salts have been studied by Dr. J. E. Wertz (Minnesota). Large variations in line-width were observed. For example, addition of zinc chloride to aqueous sodium chloride broadens the chloride ion resonance. This is explained by interaction of the zinc ion with the chloride ion, which destroys the spherical charge distribution of the latter, resulting in quadrupole broadening of the resonance line.

The experimental problem of obtaining reliable chemical shift data has been extensively investigated by Dr. Zimmerman. Errors due to sample shape and to the use of internal reference standards were considered. It was recommended that external reference standards be used in connexion with a coaxial sample tube made from precision tubing. Dr. Bothner-By has made a thorough study of the effect of bulk magnetic susceptibility of the sample on the measured chemical shift. The effect, measured directly for a large series of aliphatic compounds and binary solutions, was found to be about 26 per cent greater than that calculated theoretically. With aromatic compounds there is a further anomalous behaviour which can be satisfactorily accounted for in terms of the induced 'ring' current mentioned earlier.

W. G. Schneider

INTERNATIONAL GENETICS SYMPOSIA IN JAPAN

During September 6–12 the Science Council of Japan was host to two International Genetics Symposia: one on "Applied Genetics", sponsored by the Science Council itself, and one on "Physical and Chemical Approaches to Problems in Chromosomes", sponsored by the International Union of Biological Sciences. The latter had been originally suggested by the International Genetical Society at its last conference at Bellagio, Italy.

The two symposia were held concurrently, at Tokyo and Kyoto. They were attended by some four hundred Japanese geneticists and about a hundred from other countries, the majority of these being from the United States, although there were a few representatives of each of a large number of other nations, both European (including the U.S.S.R.) and Asian. Most of the meetings were held in a fine new building in the centre of Tokyo, the Sankei-kaikan, where there are many small lecture rooms and also a large hall.

On the first morning of the conference, addresses of welcome were given by Dr. H. Kihara, the chairman of the organizing committee, by Drs. S. Kaya and T. Komai, representing the Science Council and Japanese geneticists respectively, and by the Ministers of Education and of Welfare; a reply on behalf of the foreign participants was made by Dr. R. E. Cleland. The conference then got down to business, with a simulating and lucid discussion by Dr. G. W. Beadle on the complicated problem of "Gene Function and Gene Structure", followed by a most valuable general summary, by Y. Tanaka, of the development and present state of genetics in Japan.

On the following days, the conference met in plenary session for general lectures in the mornings, and in separate smaller groups for papers on more specialized topics in the afternoons. The comparatively large number of these sectional groups (about ten) made it impossible for any participant to listen to more than a small fraction of the whole conference, but any disadvantages which might arise from this were, to a large extent, made up for by the excellent facilities for personal meetings and conversations. Not only did most of the lecture rooms open off a large lounge, but our Japanese hosts offered us a number of most delightful informal meals, visits to exhibits, and excursions. Indeed, it is not too much to say that the enormous amount of work which had been devoted to preparing really informative and thorough exhibits, combined with the exceptionally smooth organization of a series of functions which encouraged individual contacts, made this conference one of exceptional value. No one fortunate enough to see the exhibits on silkworm genetics at the State Sericultural Experiment Station, the work on rice at Hiratuka, on the morning glory at Misima, and the series of exhibits on wheat, radish and goldfish at Kyoto, will have failed to carry away a lasting impression of the peculiar strengths of Japanese genetics. Nor shall we easily forget the seedless water-melons offered us at the Institute organized by Dr. Kihara, their originator, at Yokohama.

Of the more social entertainments, which, as has been already mentioned, played a very important part in the general success of the meeting, some may have been most impressed by the visit to a Kabuki theatre, others perhaps by the trip to the famous architectural show-piece at Nikko. Personally, I think I shall treasure even more the dinner offered us on the first evening at a restaurant named the Hosigaoka-saryo. The banal word 'restaurant' conveys little of the reality of this place. The establishment is, more nearly, a park extending up a steep hill below which the lights of Tokyo stretch glittering towards the horizon. Perched on ledges of the hill are temporary marquees, and permanent pavilions with interiors of the fresh purity of line and colour characteristic of classical Japanese building. In one of these there was Japanese dancing, in another Chinese dishes were to be had, but the centre of attraction was a large terrace at which we were offered an initiation, as thorough as one wished to make it, into the delights of the Japanese cuisine. Attempts to master the trick of managing *hachi* (chopsticks), to identify the delicious but unexpected items of sea-food in the deep-fried fritters known as *tempura*, or the algae or other materials used for wrapping and flavouring the rice balls called *sushi*, to discuss whether the rice-wine *sake* is nicer warm or cold, and if it is really quite strong or not strong at all—such things provided the perfect recipe for breaking the ice on the first day of what proved one of the most pleasant and valuable occasions of international contact which has been held in the biological world for many years.

C. H. WADDINGTON

USE OF ANTIBIOTICS AGAINST PLANT DISEASES

THE title gives the theme of a symposium held on September 28 by the Association of Applied Biologists. The symposium, of eight papers, was mainly devoted to the action of two antibiotics, streptomycin and griseofulvin. The latter, a fungistatic substance produced by *Penicillium* spp., has been used solely against plant diseases. Streptomycin produced by *Streptomyces* spp., on the other hand, was originally used in medical research and has only recently been extensively tested against bacterial diseases of plants.

In some of the experiments discussed, the effects of these antibiotics might have been caused by their action at sites remote from the point of application—a property which contrasts with the action of contact fungicides at or near the point of application only.

In his paper, Mr. S. H. Crowdy (Jealott's Hill Research Station) gave proof that both these antibiotics are absorbed from culture solutions by roots of uninfected plants, and that the amount of griseofulvin taken up is simply related to the amount of water transpired and the concentration in the solution. Once within the plant, their fates vary from one host species to another. The greater proportion of griseofulvin taken up by tomatoes stays in the roots, whereas in broad beans the majority moves from the roots and is found in the lower leaves; little is found in the stems of either plant. In contrast, streptomycin accumulates freely in tomato shoots, but only traces are found in the base of broad bean shoots even after prolonged treatment. Similarly, Lelliott found that streptomycin moves only very slowly from the base of carnation cuttings, and even though the cuttings were in streptomycin solutions containing 100 p.p.m. for only 24 hr., its presence could still be detected after 73 days. The rate of decay of griseofulvin in broad beans is relatively constant—there is a straight-line relation between the logarithm of the percentage griseofulvin surviving and time; 50 per cent of the griseofulvin disappears within 5 days.

Griseofulvin affects the development of a wide range of fungal and allied diseases, for example, those caused by *Plasmodiophora brassicae*, *Fusarium* spp., *Erysiphe* spp. and *Botrytis* spp. Adding griseofulvin to mixtures of unsterilized soil and sand inoculated with resting spores of *P. brassicae* decreases the number of root-hair infections on cabbages, the percentage plants clubbed and the size, at least temporarily, of the clubbed roots. In common with the standard fungicides, griseofulvin is most effective against low concentrations of inoculum. Where griseofulvin is only sufficient to reduce club size temporarily, eventually, when its retarding effect has disappeared, bigger clubs are produced than on the untreated plants. Associated with the larger clubs is a greater weight of foliage. This result probably reflects the ability of large plants when inoculated—in this experiment equivalent to when the griseofulvin no longer inhibited—to develop bigger clubs with less disruption than small plants.

The effects of soil applications of griseofulvin given three weeks after inoculation suggest that it can act systemically against *P. brassicae*. By then infection had occurred and the early stages of club formation within the root cortex were probably taking place. A week later clubs were seen only on the untreated controls, and after a further four weeks the clubs on the untreated controls were still five times larger than on the treated plants (Drs. F. T. Last and I. Macfarlane, Rothamsted Experimental Station).

Further evidence of its systemic properties was given by Dr. A. Rhodes and Messrs. R. Crosse and R. McWilliam (Glaxo Laboratories, Ltd.), who controlled chrysanthemum powdery mildew, a leaf disease caused by *Oidium chrysanthemi*, by watering the roots with a wettable powder formulation of griseofulvin. Although no attempt was made to give equal amounts of active principle, soil applications were more effective than foliage sprays. Sprays containing 0·025 per cent griseofulvin were as effective as 'karathane' (dinitro capryl phenyl crotonate) sprays containing 0·05 per cent active principle.

Two sprays containing 0·025 per cent griseofulvin, one prepared with a wettable powder and the other with an NN-dimethylformamide liquid concentrate, were equally effective against chrysanthemum powdery mildew. The efficacy of the griseofulvin, however, was less in the wettable powder formulation since the powder alone gave significantly greater control of mildew than NN-dimethylformamide. In other small plot tests, griseofulvin controlled the incidence of *Botrytis cinerea* on lettuce and *B. tulipae* on tulips. In the control of the latter disease, tulip fire, under commercial conditions, griseofulvin sprays were more effective than 'Ferbam' sprays (ferric dimethyl dithiocarbamate) when compared weight for weight of active principle.

The results of experiments done in artificial and natural conditions do not invariably agree. Mr. J. Drew Smith (Sports Turf Research Institute) has found in preliminary trials that spray applications (0·044–0·088 per cent griseofulvin) to turf, before inoculation with *Fusarium nivale* and *Sclerotinia homoeocarpa*, give very effective control of their respective diseases, *Fusarium* patch and dollar spot. In field trials relying on natural infection, however, they appear less effective and do not give as good control as mercury and cadmium fungicides. The apparent drop in the efficiency of griseofulvin may be attributable to changes in its formulation.

Similarly, the field-results using streptomycin do not always confirm the promise shown by initial tests. Of the two materials, streptomycin and 'Agrimycin' (1 : 10 mixture of oxytetracycline and streptomycin), the former was used against *Pseudomonas caryophylli*, the cause of bacterial wilt of carnations, and the latter against *Erwinia* sp., the cause of slow wilt of carnations. The highest minimal bactericidal dose recorded for a range of isolates was 5 p.p.m. of streptomycin against *Ps. caryophylli* and 3 p.p.m. of 'Agrimycin' against *Erwinia* sp.

The effects of these antibiotics on their respective diseases vary with the substrate in which the crops are, when they are applied. By standing a mixture of healthy and infected cuttings in solutions of 50–100 p.p.m. for 24 hr., both materials eliminate transmission but do not cure the infected plants. However, solutions of 'Agrimycin' of similar concentrations do not significantly reduce the spread of slow wilt when watered to cuttings rooting in sand.

The discrepancy between the effective bactericidal doses of both streptomycin and 'Agrimycin' against their respective pathogens in culture and on the host may be attributed to many factors. As with some of the standard fungicides, for example, chloronitrobenzenes, the efficacy of the antibiotics may be affected by the substrate on which the test organism is growing (Mr. R. A. Lelliott, Plant Pathology Laboratory, Ministry of Agriculture, Fisheries and Food).

The effect of streptomycin on bacterial canker of cherry caused by *Pseudomonas mors-prunorum* varies with the stage in the host's development at application. Spraying trees with streptomycin hydrochloride (220 p.p.m.) during the spring blossom period has a large immediate effect in reducing the severity of the necrotic leaf-spotting phase of the disease, but has little persistent effect on the supply of inoculum available for infection of branches in the autumn, as measured by the numbers of bacteria present on the leaf surfaces. Autumn sprays of streptomycin reduce the amount of leaf-surface inoculum, but less effectively than 'low'-strength Bordeaux mixtures. However, despite its apparent inferiority as a surface bactericide, streptomycin is almost as effective in reducing branch infections as Bordeaux mixture. Unequivocal evidence of the systemic activity of streptomycin was not obtained, although the effects of the spring sprays for the control of the leaf-spot phase may be partly attributed to this mode of action (Dr. J. E. Crosse, East Malling Research Station).

At this symposium, there was ample evidence to show that griseofulvin and streptomycin can reduce the severity of a range of plant diseases, and in some trials, notably against chrysanthemum powdery mildew, tulip fire and the silvering disease of beet, the antibiotics were at least as effective as, if not more effective than, the materials at present in general use. The seed-borne organism causing silvering disease of beet, *Corynebacterium betae*, was as effectively controlled by soaking seeds in streptomycin solutions at 200 p.p.m. for 24 hr. as by dusting them with mercury fungicides (Dr. W. G. Keyworth, National Vegetable Research Station).

To gain the maximum advantage from these materials, emphasis should be turned to studying their accumulation within the host in relation to possible disease control. Thus with tomatoes, which accumulate griseofulvin in the roots, the probability of control is greater with root- than with leaf-infecting parasites.

Their use, as with most chemicals, does, however, present a number of hazards. Concentrations of griseofulvin unnecessarily high for the control of clubroot damaged cabbages, and the root growth of carnation cuttings, stood for 24 hr. in streptomycin solutions, progressively decreased as the concentration increased above 50 p.p.m. Rooting hormone can, however, be used as an antidote to this latter effect.

Apart from their harmful effects to plants when used indiscriminately, they may in addition detrimentally affect the health of man, a fact stressed by Dr. R. A. Shooter (St. Bartholomew's Hospital, London). In medical practice, some people, principally those dealing daily with its administration, have developed a sensitivity to streptomycin, and so cannot now avail themselves of its beneficial properties against disease unless de-sensitized. This risk has since been much reduced by making simple alterations in the handling technique. Apart from the preparation of sprays, the risk of developing sensitivity to antibiotics, if used as plant protectants, may arise from exposure to spray drift. It is, however, probably much less than in medicine, since the concentrations used are much lower. The effects described of streptomycin against plant diseases were caused by 0·02 per cent solutions; in medicine, preparations containing 10 per cent are used. Although no examples of sensitization from handling antibiotics included in animal feeding stuffs were quoted during the symposium, the effect of consuming residues persisting on and in sprayed food is still a matter of conjecture and needs investigating.

These two hazards, toxicity to plants and sensitization of man, can be minimized by (*a*) thorough research before making recommendations and (*b*) by careful handling techniques. Already streptomycin is being used against plant diseases in New Zealand and the United States. A possible third hazard, the development of parasites resistant to antibiotics, is, however, less readily combated. Although the minimal dose of a material necessary to kill or inhibit the growth of parasites *in vitro* may be known, it is impossible to maintain such concentrations continuously *in vivo*. Thus conditions occur in which the concentrations of antibiotics are sub-lethal or sub-inhibitory, and in which adjustments in the population of parasites may take place. Although this type of adaptation has not been a serious problem in the control of plant pathogens with standard fungicides in the field, in medicine, and especially with the antibiotics, it causes great difficulties. As yet, antibiotics have been used against plant disease in the field for too short a time to assess the magnitude of this hazard.

F. T. Last

INDUSTRY AND THE TECHNICAL COLLEGE IN BRITAIN

THE handbook entitled "Industry and the Technical Colleges"*, which has been issued by the Joint Federation of British Industries–Technical Colleges Committee under the auspices of the Federation's Education Committee, is based on papers prepared by the Committee as a sequel to discussions at a conference convened by the Federation in May 1954 between representatives of industry and the technical colleges. Among the points covered at the conference were co-operation between industry and the technical colleges, flexibility in technical education, recruitment from the secondary schools, the supply of teachers, sandwich courses, advanced short courses in applied science and technology, research in technical colleges, technological careers for women, the technical college and education for management, and equipment in technical colleges. The handbook, which is published as a contribution to the public discussion of these important issues, sets forth the views and recommendations of the Joint Committee.

Recognizing that a growing proportion of the technicians and technologists required by industry in Britain will come from the technical colleges, the handbook urges the need for greater co-operation, both formal and informal, between industry and the technical colleges: unless they are aware of each other's activities, the colleges will be unable to provide what is needed and industry will not reap the full benefit of the resources available. Accordingly, the Committee recommends that directors and senior executives should be prepared to serve on governing bodies, advisory committees and regional councils and that firms should plan training programmes in close consultation with colleges and expand part-time day release wherever possible. The colleges are recommended to review, where appropriate, the composition and terms of reference of governing bodies and advisory committees, and to adjust courses and teaching methods to the changing needs of industry. They should also encourage the secondment of teachers to industry, and firms are recommended to make available qualified members of their staff for part-time teaching.

As regards courses, firms are recommended to assist actively the development of 'sandwich' courses, and small- and medium-sized firms should co-operate in jointly sponsoring appropriate specialized courses. The co-operation of industrialists in the selection of management students is essential, and firms should inform colleges and regional advisory councils of the calls for special advanced courses. On their side, the colleges should see that syllabuses of vocational courses contain a proportion of liberal subjects and should see both that secondary school boys and girls are more fully informed of their facilities and that more information about advanced courses is brought to the knowledge of industry generally. Research in technical colleges should be expanded and devoted primarily, but not exclusively, to the solution of industrial problems. Teaching staffs should be encouraged to undertake research, and industry could help by grants, gifts and loans of special equipment, and of periodicals and special publications, as well as by establishing research studentships or junior fellowships. The importance of publishing industry-sponsored research whenever possible is stressed.

The handbook recommends the employment of more women in scientific and technological work and suggests that the colleges could help here by training girls for employment in such capacities as laboratory assistants. The need for better technical equipment is also emphasized, and firms are recommended to assist by donations in cash or in kind, while the establishment by the colleges of a central clearing-house for exchange of information on offers of equipment is suggested. The importance of social amenities is likewise stressed, and any help which industry can give in this respect will be a very real contribution towards achieving the aims of technical education in Britain to-day.

---

SOCIAL AND ECONOMIC RESEARCH

A COMMITTEE with considerable if indirect influence on Great Britain's social and economic policy was set up in 1947 by the then Lord President of the Council and the Chancellor of the Exchequer. The committee is called the Interdepartmental Committee on Social and Economic Research and its members are drawn from university and government departments concerned with social and economic matters either as subjects of study and research or as branches of public administration. The Committee was given the following terms of reference and these have not been changed during the intervening years: "to survey and advise upon research work in government departments, and in particular (*a*) to bring to the notice of departments the potential value for research purposes of the material which they collect and to suggest new methods and areas of collection; (*b*) to advise on how there could be made available to research workers information gathered for their own purposes by the departments which has potential value as material for research".

The Committee has now produced its third report and, in it, surveys the recommendations it has made and the results it has achieved over the past nine years*. Various lines of approach have been used for ensuring that government departments are aware of the interest of research workers in the data assembled for administrative purposes and also in appropriate cases to suggest new methods and areas of collection. For example, general recommendations have been addressed to social and economic departments on such matters as consultation on their statistical programmes; the deposit of unpublished government papers in suitable libraries has been advocated and facilitated; the aims and activities of the Committee have been brought to the notice of a wider public through the publication of reports and "guides to official sources". The more usual procedure during the period under review, however, has been to make suggestions to particular departments after their work and the material which they collect and produce have been intensively studied by one of the specially appointed sub-committees, which are suitably strengthened for the purpose.

The second main concern of the Committee is that research workers should know what material is available and should, within reason, be helped to gain access to it. To some extent the Committee's recommendations have led to the publication of additional material by departments in annual reports or otherwise. The Committee itself has published several "Guides to Official Sources"; has circulated to a select list of university and other research libraries particulars of unpublished material which departments are willing to make available to the libraries; and, on a few occasions, the Committee has been able to put individual research workers in touch with the appropriate departmental officers.

---

* Report of the Interdepartmental Committee on Social and Economic Research (H.M.S.O., 1956).

In earlier reports the Committee emphasized how difficult it sometimes was for the research worker to discover what material of relevance to his studies actually existed in government departments and how these could be made available.

Recent investigations suggest that, in general, departments publish statistics more freely than they used to and are usually prepared to deal sympathetically with requests for access to unpublished material in their possession.

The well-proved device of *ad hoc* sub-committees, made up of those members of the Committee with special knowledge or special interest in the subjects under review and reinforced with outside experts co-opted for the purpose, has again been the standard mode of procedure in the examination of the basic questions: what do departments collect; how far is it or could it be published or made otherwise accessible to students; and are there changes in present methods or treatment of the material that seem worth making in the department's own interest on one hand or in that of research workers on the other?

The work of four such sub-committees during 1951–55 is covered by the present report. They were concerned with the Board of Trade; with the proposed content of statistical tables for the reports of the 1951 Census; with local government statistics relating particularly to finance; and with the Ministry of Food.

Recommendations made to departments during the five years ranged widely. Patents, company records, insurance and bankruptcy statistics, as well as statistics relating to the administration of enemy property, are among the subjects on which recommendations were made to the Board of Trade; the Committee also conveyed its views to the Board on the question of publishing selected papers on foreign economic relations.

The registrars general were advised on tables for information obtained by the 1951 Census on birthplace and nationality, education, classification by social class, the cross-classification of occupation within industries, fertility, housing and the characteristics of private households. The Committee also made suggestions for detailed census statistics of the large conurbations (Greater London, west Midlands, south-east Lancashire, Merseyside, west Yorkshire, Tyneside and central Clydeside).

Recommendations were made to those departments concerned with local services and which publish, either in their annual reports or as separate returns, a wide range of local government statistics on such matters as finance, health education, child care, police and fire services and local elections.

The broad nature of the survey of Ministry of Food material did not preclude the committee from making recommendations on points of detail. The report refers to statistics of food supply and procurement, home production, processing and manufacture; stocks; the distribution and use of food; the administration of food controls; prices and margins; and household food surveys. In particular, the Committee pointed to the research interest in the continuance of the National Food Survey and advocated two publications on statistics of food and agriculture: a periodical for current figures and a further addition to the series of "Guides to Official Sources".

The report touches on the relevance to the Committee's work of the recommendations of the Grigg Committee on departmental records, and also emphasizes the importance to research in the social sciences of being able to obtain comparable statistics from each part of the United Kingdom. In the latter connexion, reference is made to the recent production by departments of a key to differences between English and Scottish statistics of crime.

This report serves as a reminder of the need for close co-operation between departments, as the gatherers and producers of information (particularly statistical data) on almost every aspect of economic and social conditions, and the universities and research institutes which can also use that material for the common good.

TREATMENTS AFFECTING FREE ENDOGENOUS GROWTH-SUBSTANCES IN PLANTS

BECAUSE they considered that the possible effects of synthetic auxins and anti-auxins on the metabolism of indole-3-acetic acid have been inadequately studied, L. J. Audus and R. Thresh have investigated the effects of such synthetic substances on the levels of free endogenous growth-substances in plants (*Ann. Bot.*, N.S., 20, 79, 439; 1956). Seedlings of peas, beans and sunflower were treated with the synthetic auxin, 2,4-dichlorophenoxyacetic acid, and two supposed anti-auxins, 2,3,5-tri-iodo-benzoic acid and maleic hydrazide, at non-toxic levels sufficient to cause well-marked growth responses. Estimates of the content of alcohol-extractable growth-substances were afterwards determined, after separation by paper partition chromatography. Six active natural compounds were indicated in these extracts, but only the effects of treatments on indole-3-acetic acid levels have been followed in detail.

As 2,4-dichlorophenoxyacetic acid treatment of both leaves and roots had no detectable effect on the levels of free endogenous indole-3-acetic acid, the authors conclude that it is an auxin in its own right and does not act on growth by disturbing the indole-3-acetic acid metabolism. There are indications that considerable amounts of the absorbed 2,4-dichlorophenoxyacetic acid are converted in plant tissues to a neutral detoxication product which is easily decomposed to liberate 2,4-dichlorophenoxyacetic acid during chromatographic analysis. Treatment of pea roots by 2,3,5-tri-iodo-benzoic acid is very effective in reducing their free endogenous indole-3-acetic acid content, in some cases to 1/10,000 the normal level. The implications of these findings are discussed in terms of the physiological and morphological responses of plants to 2,3,5-tri-iodo-benzoic acid treatment. The authors state that maleic hydrazide may increase slightly the level of free endogenous auxin in pea roots but that further confirmatory work is required.

THE FLIGHT OF VERY SMALL INSECTS

By G. A. HORRIDGE
Gatty Marine Laboratory, St. Andrews

EXPERIMENTAL work on the flight of insects has in general confirmed the view that the wing of an insect in flight acts as an aerofoil[1]. However, there are available aerodynamical results[2] which indicate the existence of a lower limit to the size of an insect wing which can act effectively as an aerofoil. This proves to be near the observed limit of known wings of normal shape, though the structure of certain very small wings indicates a different mechanism of flight.

Accurate measurements of the forces on an aerofoil at very low speeds have been made by Thom and Swart[2]. Working with aerofoil *RAF 6A*, 1·24 cm. chord, 7·5 cm. span, they were able to make measurements in oil down to Reynolds numbers less than unity (calculated on the chord). It was discovered that below $R_e = 10$ the lift is no longer proportional to the square of the velocity for a given angle of incidence, but becomes proportional to the velocity of the free stream. Similarly, the drag coefficient begins to increase at $R_e = 10$, and reaches a value greater than 10 for $R_e = 1$, whereas it is about 0·5 for $R = 100$. The most relevant aspect of these results for insect flight is the ratio, recalculated from their results, of the drag forces to the lift forces, and this is plotted for various values of Reynolds numbering in Fig. 1.

It is clear from the graph that the Reynolds number must be greater than 100 if the inertial components, which ultimately produce the lift, are to be significantly greater than the viscous components, which are responsible for the drag. This means that at Reynolds numbers less than 100 the aerofoil is progressively ceasing to act in the manner that we normally expect at high Reynolds numbers.

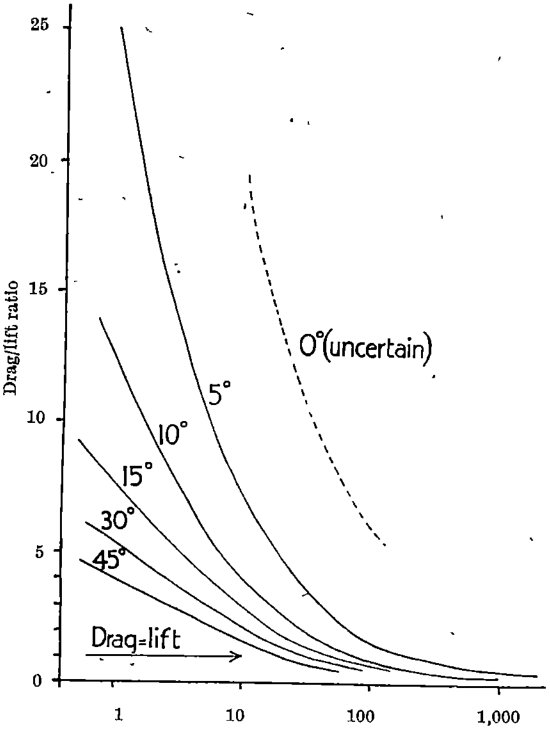

Fig. 1. The ratio drag/lift for various values of Reynolds number and a range of angles of incidence. Calculated from Thom and Swart (ref. 2)

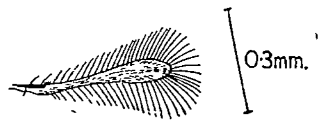

Fig. 2(*a*). Fore-wing of *Anagrus incarnatus incarnatus* Haliday from Debauche (ref. 5)

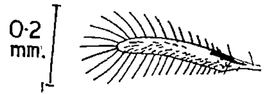

Fig. 2(*b*) Fore-wing of *Anaphes augustipennis* Debauche

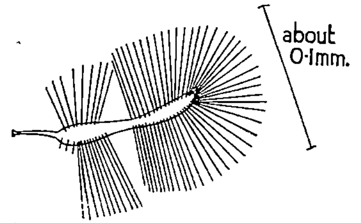

Fig. 2(*c*). Wing of the beetle *Oligella foveolata* Allib. (after Flach, ref. 6)

Now if the values of the Reynolds numbers for various sizes of insect wings with a possible range of frequencies $50 < f < 250$ are calculated, numbers less than 100 appear for the lower ranges of frequency and wing chord. The values calculated in Table 1 are based on a length/breadth ratio of 4/1 (Reynolds number calculated on the chord). As a value for the effective velocity, it is assumed that the wing moves through a distance twice its length (up and down) multiplied by its frequency. This estimate of Reynolds number inclines towards a high value, and for wings of length/breadth ratio 2/1, as in Fig. 2, the results for corresponding numbers are a half of those given.

The smallest insect wings come in a size-range where the Reynolds number alone makes them very inefficient as an aerofoil. I have not been able to discover any figure for the frequency of the wing-beat of the forms illustrated in Fig. 2, but it is unlikely that it will be above the range considered in Table 1. The peculiar fact that such small wings are made of bristles instead of a continuous membrane was noticed by D'Arcy Thompson[3], who suggested that viscous forces play a large part in the action of such wings. The convergence between the hymenopteran mymarid wings (Fig. 2*a* and 2*b*) and

Table 1. Approximate Values of Reynolds Number for Small Wings of Various Breadths
It is assumed for the effective velocity that the wing moves through a distance twice its length multiplied by the frequency per second

Length–breadth ratio = 4

Wing-breadth (mm.)	Frequency/sec. 50	100	150	200	250
0·1	3	6	9	12	15
0·2	12	24	36	48	60
0·4	48	100	150	200	250
0·8	200	400	600	800	
1·6	800				
3·2			$R_e > 1,000$		

the beetle *Oligella* (Fig. 2*c*) is noteworthy. These examples are some of the smallest insect wings, and it seems that they must be operating in the range where viscous drag forces are several times any possible lift forces. It is probable that they have abandoned altogether the aerofoil action and that they literally 'swim' in the air.

Flight would still be possible in these circumstances if there were some mechanism by which the drag on the upstroke is made less than that on the downstroke. If the ratio of downstroke drag to upstroke drag is greater than, say, 5/4, the net upward force from this source would be of the same order as the lift derived from an aerofoil action. A possible mechanism would be to have bristles or a whole wing that bends more easily on the upstroke than on the downstroke. From Thom and Swart's data, it appears that a twist of the wing would not suffice, because the drag at low Reynolds numbers becomes independent of the angle of incidence. Whatever the mechanism, it must be very wasteful of energy.

It is an interesting fact that some of the Mymaridae can 'fly' underwater, using their wings at a frequency of about two beats per second[4], for which there must be some kind of differential drag mechanism.

A feature of Thom and Swart's results is that high angles of incidence up to 45° are effective in producing lift at very low Reynolds numbers. Fig. 1 shows that a lower drag/lift ratio is achieved by high angles of incidence in the range $10 < R_e < 1{,}000$. It is tempting to consider here the general tendency for small insect wings to be without the veins which stiffen their posterior edges. This produces a greater flexibility of the trailing edge and agrees with the lift improvement at high angles of incidence, if at the same time they have given up the active twist of the wing and 'swim' through the air in much the same way as a fish if it had only a passive tail flap. The opinions here advanced can only be confirmed by observation of the insects in question; but the aerodynamical results at low Reynolds numbers certainly indicate a lower size limit to the action of an aerofoil.

BILIRUBIN, AN UNCOUPLER OF OXIDATIVE PHOSPHORYLATION IN ISOLATED MITOCHONDRIA

By Dr. R. ZETTERSTRÖM and Dr. L. ERNSTER

Pediatric Clinic, Karolinska Sjukhuset, and Wenner-Grens Institut, University of Stockholm

JAUNDICE, due to an accumulation of indirect bilirubin according to the van den Bergh reaction (recently established to consist of free, non-conjugated bilirubin[1,2]), is a relatively common and harmless phenomenon in new-born infants whose liver function is not yet fully developed. In prematurely born infants[3], however, or in those born with a hæmolytic disease (for example, that due to iso-immunization), hyperbilirubinæmia may attain an extremely high degree. In such cases, regardless of the etiology of the hyperbilirubinæmia[4], a syndrome of severe brain damage may develop, called kernicterus, or bilirubin encephalopathy[5]. It is also known that high levels of indirect serum bilirubin may lead to liver dysfunction[6,7]. These facts have directed attention to the possibility that free bilirubin might exert a toxic action on tissue metabolism. Working with brain homogenates, Day[8] and Waters and Bowen[9] have recently demonstrated decreased respiration in the presence of bilirubin—an effect which could be reversed[8] by the addition of cytochrome *c* or diphosphopyridine nucleotide[10]. In the present communication evidence is presented that bilirubin uncouples phosphorylation from respiration in isolated liver mitochondria and causes, as a secondary effect, a release of respiratory cofactors, such as diphosphopyridine nucleotide and cytochrome *c*, from the mitochondrial structure.

The experiments were performed with liver mitochondria prepared from white rats (Wistar) according to the method of Schneider and Hogeboom[11]; details of the preparation have been described elsewhere[12]. Mitochondria from one liver, washed twice with 0·25 *M* sucrose, were suspended in 20 ml. of a solution containing 0·15 *M* potassium chloride, 0·05 *M* potassium orthophosphate (*p*H 7·5), 0·001 *M* disodium adenosine triphosphate and 0·06 *M* glucose. The suspension was supplemented with 2 ml. 0·1 *M* magnesium chloride and with an excess of yeast hexokinase, and made up to 30 ml. with 0·25 *M* sucrose. Aliquots of 1·5 ml. of this suspension were added to Warburg vessels containing 30 micromoles substrate and further additions to be tested. The final volume in each vessel was adjusted to 2 ml. with 0·15 *M* potassium chloride. Oxygen consumption was measured at 30° C. for 15 min., including 5 min. of thermoequilibration; the oxygen consumption for this period was calculated by extrapolation. After the manometric recording, the samples were fixed with 0·5 ml. 50 per cent trichloroacetic acid and filtered. Phosphate uptake was estimated in 0·1-ml. aliquots of the filtrates by the isotope distribution method described elsewhere[13]. For the determination of adenosine triphosphatase activity, mitochondria from one liver were suspended in 30 ml. of 0·25 *M* sucrose. Aliquots of 1 ml. were added to 50-ml. Erlenmeyer flasks containing 2 ml. of 0·016 *M* disodium adenosine triphosphate in 0·25 *M* sucrose, 0·4 ml. of 0·5 *M* *tris*(hydroxymethyl)amino-methane buffer (*p*H 7·5), 0·2 ml. of 0·1 *M* magnesium chloride and 0·4 ml. of 0·1 *M* potassium chloride including the individual additions to be tested. When the effect of hypotonicity was to be investigated the mitochondria were suspended in 0·025 *M*, rather than 0·25 *M*, sucrose, and incubated at 30° C. for 15 min. before being added to the reaction mixture.

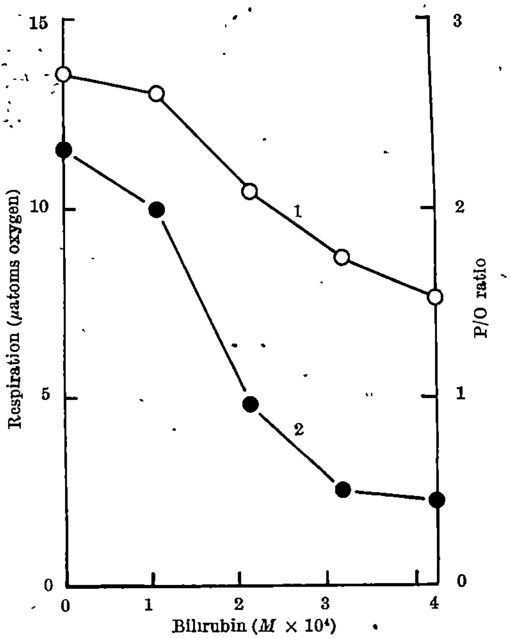

Fig. 1. Effect of varying concentrations of bilirubin on oxidative phosphorylation supported by glutamate. Curve 1, O—O, respiration; curve 2, ●—●, P/O ratio

Each Warburg vessel contained: mitochondria from 1/20 liver, 30 micromoles potassium L-glutamate, 50 micromoles potassium orthophosphate (pH 7·5), 1 micromole disodium adenosine triphosphate, 60 micromoles glucose, 10 micromoles magnesium chloride, 200 micromoles potassium chloride, 100 micromoles sucrose, and 25 microlitres of a stock solution of yeast hexokinase (cf. ref. 16), in a final volume of 2 ml. Gas phase, air; centre well, 0·2 ml. 2 M potassium hydroxide. Temp., 30° C. Time of incubation, 15 min.

The flasks were incubated at 30° C. with gentle shaking. Samples of 1 ml. were removed at 0, 10 and 20 min. and added to 2 ml. of ice-cold 10 per cent perchloric acid. After filtration, orthophosphate was determined in 1-ml. aliquots by the colorimetric method adapted[14] from Martin and Doty[15].

Solutions of bilirubin were prepared by dissolving 10 mgm. crystalline bilirubin (Merck Chemical Co., Darmstadt) in 2 ml. of 0·2 M potassium hydroxide and adjusting the pH to just below 8 by the dropwise addition of 1 M hydrochloric acid. The solution was made up with water to 4 ml. and further diluted, when desired, with 0·1 M-potassium chloride. Biliverdin was obtained by exposing an alkaline solution of bilirubin to oxidation in air, the colour shift being controlled spectrophotometrically.

Table 1. EFFECT OF BILIRUBIN ON OXIDATIVE PHOSPHORYLATION SUPPORTED BY VARIOUS SUBSTRATES

Substrate, 30 micromoles. Bilirubin, 4·3 × 10^{-4} M. Other experimental conditions as in Fig. 1

Substrate	Without bilirubin		With bilirubin	
	Oxygen (µatoms)	P/O ratio	Oxygen (µatoms)	P/O ratio
L-Glutamate	12·1	2·79	7·6	0·54
α-Ketoglutarate	10·1	2·83	12·0	0·67
Succinate	12·3	1·53	8·4	0·24
Pyruvate + 3 µmoles L-malate	12·2	2·58	12·0	0·42
DL-β-Hydroxybutyrate	8·1	2·58	9·1	0·43

Table 2. COMPARISON OF THE EFFECTS OF BILIRUBIN AND BILIVERDIN

Experimental conditions as in Fig. 1. Bilirubin or biliverdin, 4·3 × 10^{-4} M

Addition	Oxygen (µatoms)	P/O ratio
None	13 6	2·32
Bilirubin	7·6	0 45
Biliverdin	13·0	2·63

Fig. 1 shows the effect of varying concentrations of bilirubin on oxidative phosphorylation supported by glutamate. At a concentration of about 3 × 10^{-4} M, bilirubin causes an almost complete inhibition of phosphorylation, accompanied by a partial inhibition of respiration. As shown in Table 1, a similar picture is obtained if glutamate is replaced by α-ketoglutarate, succinate, pyruvate or β-hydroxybutyrate, although the effect on respiration may be less pronounced, or even absent. Among derivatives of bilirubin, so far only biliverdin has been tested and found, as shown in Table 2, to be without effect on either respiration or phosphorylation.

Table 3. EFFECT OF BILIRUBIN ON MITOCHONDRIAL RESPIRATION UNDER VARIOUS CONDITIONS

Experimental conditions as in Fig. 1. Additions: bilirubin, 4·3 × 10^{-4} M; diphosphopyridine nucleotide, 6·8 × 10^{-4} M; cytochrome c, 10^{-5} M; 2,4-dinitrophenol, 10^{-4} M

Additions	Without hexokinase	With hexokinase	
	Oxygen (µatoms)	Oxygen (µatoms)	P/O ratio
None	2·3	13 6	2·32
Bilirubin	5·1	7 6	0·45
Bilirubin + diphosphopyridine nucleotide		11·6	0·42
Bilirubin + cytochrome c		10·9	0·40
Bilirubin + diphosphopyridine nucleotide + cytochrome c	13·8	13 9	0·43
2,4-Dinitrophenol	13·7	14 1	0·33

In Table 3 some further effects of bilirubin on mitochondrial respiration are demonstrated. The partial inhibition of respiration, found at higher concentrations of bilirubin, can be prevented by the

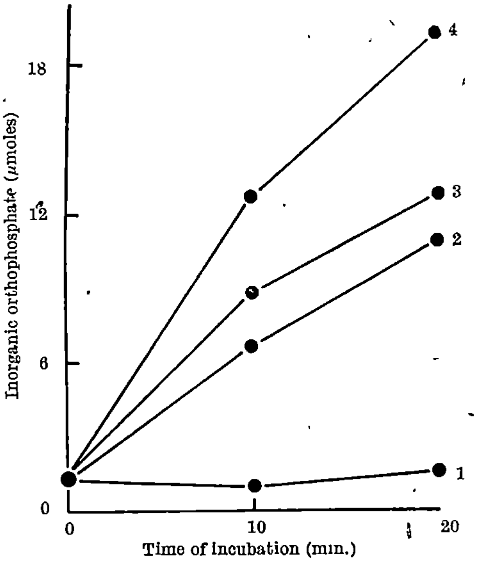

Fig. 2. Effect of bilirubin on mitochondrial adenosine triphosphatase activity

Each of the four series contained: mitochondria from 1/30 liver, 32 micromoles disodium adenosine triphosphate, 20 micromoles magnesium chloride, 200 micromoles *tris*(hydroxymethyl)aminomethane buffer (pH 7·5), 40 micromoles potassium chloride, and 750 (in series 3, 525) micromoles sucrose, in a final volume of 4 ml. Incubation at 30° C.

Series 1, no addition or pretreatment; 2, 4·3 × 10^{-4} M bilirubin added; 3, no addition; mitochondria pretreated with 0·025 M sucrose at 30° C. for 15 min.; 4, 10^{-4} M 2,4-dinitrophenol added combined addition of diphosphopyridine nucleotide and cytochrome *c* (or by cytochrome *c* alone in the case of succinate); but these additions fail to prevent the effect of bilirubin on phosphorylation, the phosphate/oxygen (P/O) ratios being invariably low. This indicates that the primary action of bilirubin consists in an uncoupling of phosphorylation from respiration. The loss of the respiratory cofactors, diphosphopyridine nucleotide and cytochrome *c*, may be a secondary consequence of this effect, possibly due to a labilization of the mitochondrial structure. A similar phenomenon has recently been demonstrated to occur when 2,4-dinitrophenol is acting as an uncoupler of phosphorylation in a mitochondrial system which has been supplemented with an extremely high level of hexokinase[16]. Bilirubin seems, however, to be more potent in evoking this secondary effect than is dinitrophenol.

A further indication that bilirubin acts primarily as an uncoupler of phosphorylation from respiration emerges from the fact, also shown in Table 3, that it, like dinitrophenol, is able to induce a maximum level of respiration in mitochondria that have been incubated in the absence of hexokinase, that is, the respiration of which is limited by the lack of a terminal phosphate acceptor[17]. Finally, as illustrated by Fig. 2, bilirubin is a potent inducer of adenosine triphosphatase activity in mitochondria, its action being similar, even in this respect, to that of dinitrophenol[17]. The adenosine triphosphatase activity elicited by bilirubin is, however, lower than that obtained with dinitrophenol; it is of about the same level as that which arises in mitochondria upon ageing in hypotonic medium.

On the basis of the present results, it is concluded that bilirubin in or above a concentration of 3×10^{-4} *M* uncouples phosphorylation from respiration in isolated rat liver mitochondria. This effect is accompanied by a marked elevation of the mitochondrial adenosine triphosphatase activity, and by a release of diphosphopyridine nucleotide and cytochrome *c* from the mitochondria, resulting in a decrease of the respiratory-rate. Although the effect of bilirubin is, at least in the two former respects, similar to that of 2,4-dinitrophenol, bilirubin seems to act more directly on the mitochondrial structure and, thus, it would appear to be premature to consider a common mode of action of the two agents. It is noteworthy that the concentration-range in which bilirubin exerts its action on mitochondrial oxidative phosphorylation coincides very closely with the level (20 mgm. per cent) at which serum bilirubin is known to become critical to the new-born infant[18]. Further aspects, clinical and biochemical, of the present findings are being investigated.

EFFECT OF METHYLTRYPTOPHAN AND THIOURACIL UPON PROTEIN AND RIBONUCLEIC ACID SYNTHESIS IN CERTAIN HIGHER PLANTS

By Dr. B. KESSLER

Division of Horticulture, Agricultural Research Station, Rehovot, Israel

THAT nucleic acids are involved in protein synthesis in micro-organisms is at present fairly well agreed. A study of several aspects of the nucleic acid metabolism of fruit trees has given results which throws some light on the relation of nucleic acids to protein metabolism in higher plants.

In previous unpublished work carried out in this laboratory, uracil and xanthine had been found to induce the synthesis of ribonucleic acid and of protein in several species of fruit trees. It was now of interest to study the effect of inhibitors of the purine and protein metabolism in plants in which this synthesis of ribonucleic acid and protein were induced.

From four groups of selected branches of olive trees and grape vines, each group comprising four replicates, one was kept for control and three were sprayed with a 50 p.p.m. solution of uracil. Three days later two of these groups were additionally sprayed with DL-5-methyltryptophan and 2-thiouracil, respectively. After two weeks, leaves were collected from each replicate, carefully washed with an acidified detergent, and analysed for protein and ribonucleic acid. The tissue from one set of samples was extracted with 80 per cent ethanol, and the nitrogen of the insoluble fraction was determined by micro-Kjeldahl[1]. This alcohol-insoluble N-fraction was considered as a preliminary indicator of the protein content. From a second set of samples ribonucleic acid was assayed by a modified alkali method, combining the Schmidt–Thannhauser method[2] and the method developed by Ogur and Rosen[3], in which perchloric acid was substituted for trichloracetic acid. Acid-soluble compounds were extracted with 0·2 *N* perchloric acid. The nucleic acids were extracted[4] with 1 *N* perchloric acid at 37° C., differentially fractionated by 0·35 *N* sodium hydroxide at 20° C., and then determined spectrophotometrically. The nucleic acids were

hydrolysed[5], chromatographed, and the spots were eluted and measured spectrophotometrically[6].

In the 'significant difference' row of Table 1 the treatments are arranged in decreasing order of protein and ribonucleic acid content. If significant (at 5 per cent level), the difference between two treatments is designated by a '>' symbol; '=' symbol designates a non-significant difference.

It may be seen from Table 1 that uracil induces an increased synthesis both of protein and of ribonucleic acid, and increases the molar ratio of uracil/guanine. The addition of methyltryptophan stopped the uracil-induced synthesis of protein, while that of ribonucleic acid remained unaffected. On the other hand, the ratio of uracil/guanine is somewhat decreased. Methyltryptophan is known to inhibit the incorporation of tryptophan into protein in certain tryptophan-requiring micro-organisms[4], and it might well be that the decreased synthesis of protein can be ascribed to a similar mechanism. In addition, it might be that methyltryptophan affects the ratio of uracil to guanine, which in turn affects protein synthesis. Since the total synthesis of ribonucleic acid is unaffected by methyltryptophan (that is, by decreased protein synthesis), it seems that it does not depend upon conditions conducive to protein synthesis.

With thiouracil, however, the situation was quite different. This compound, though an inhibitor of purine metabolism, caused a decrease in ribonucleic acid, in the ratio of uracil to guanine, as well as in protein; that is, the inhibited ribonucleic acid synthesis affected the protein metabolism and reduced its amount. Comparing the different effects of thiouracil and methyltryptophan upon ribonucleic acid and protein metabolism, it may tentatively be concluded that in olive trees and grape vines the synthesis of ribonucleic acid and a certain composition of it is apparently a pre-requisite for the synthesis of protein. A similar conclusion was reached with micro-organisms by several other workers[8-11]. The above results suggest that the ratio uracil/guanine, too, is likely to be an important factor for protein synthesis.

It was of interest to make a preliminary study of the way in which the above sprays affect the different amino-acid components of the proteinous fraction. The alcohol-insoluble fraction was hydrolysed with 4 N hydrochloric acid at 115° C., and analysed quantitatively by a chromatographic method developed by Thompson and Steward[12]. For the analysis of tryptophan, a separate batch of samples from each replicate was hydrolysed by alkali, and tryptophan was determined by Ehrlich's reagent. Table 2 gives typical variations of those amino-acids which were chiefly affected in olive leaves.

On the data for each separate amino-acid a standard randomized block analysis of variance was carried out (there were no significant block differences). In the 'standard error' row of Table 2, I have given the estimated error (with 9 degrees of freedom) of the treatment means. In the 'significant difference' row the treatments are arranged in decreasing order of acid content as in Table 1.

Table 2 shows that uracil increases significantly the amounts of all amino-acids reported in the table. Treatments with uracil + either methyltryptophan or thiouracil decreased all amino-acids (as compared with the treatment of uracil alone); but thiouracil caused a much larger decrease of arginine (46·2 per cent), aspartic acid (50·2 per cent), lysine (32·2 per cent) and serine (50·1 per cent) than did methyltryptophan.

Similar results were obtained with grape vines.

Further studies are in progress, and a full account of this work will be published shortly.

My thanks are due to Dr. J. Putter, who advised on the statistical analyses.

The Sun's General Magnetic Field

WITH their admirable experimental technique, Babcock and Babcock have been able to measure certain very small line displacements in the Sun's spectrum, from which they deduce a general magnetic field of the order of -1 gauss. In order to draw this conclusion they use (although implicitly) two theories: (1) the theory of the Zeeman effect, connecting the line displacements with the magnetic field in a small homogeneous volume of gas; (2) the theory of magneto-turbulence in the photosphere, which, as Babcock's 'point' measurements include many thousand granulæ, is necessary for computing the average.

Whereas the first of these is in order, the second simply does not exist at present. In an answer to criticism by Alfvén, Babcock[2] declares his belief that the effect of magneto-turbulence is small, but does not give any evidence for this point of view. There are several possible mechanisms which have a reasonable chance of occurring. One has been discussed earlier[1], and another can be demonstrated in the following simple example, which does not claim to be rigorous proof but merely serves as another illustration.

Let us consider a quasi-stationary, isothermal state where the generalized pressure is constant in space:

$$nkT_0 + \frac{1}{8\pi}(\mathbf{H}_0 + \mathbf{h})^2 = n_0kT_0 + \frac{1}{8\pi}\mathbf{H}_0^2 = \text{const.} \quad (1)$$

In equation (1) n is the particle density, n_0 its value when the turbulent magnetic field $\mathbf{h}$ vanishes, $\mathbf{H}_0$ the general magnetic field and T_0 the temperature, which is constant. The total contribution to the Zeeman displacement from a region the extension of which largely exceeds the scale of the turbulence will be given by the mean value $(\overline{nH_z})/n_0$, where the z-azis is in the direction of sight. From equation 1 the following equation is deduced:

$$\frac{\overline{nH_z}}{n_0} = H_{0z}\left[1 - \frac{\overline{\mathbf{h}^2} + \overline{2h_z^2}}{8\pi n_0kT_0}\right] \quad (2)$$

It is quite reasonable that in the photosphere the turbulent field should be so strong that the expression in parentheses becomes zero or even negative. Thus, for strong turbulent fields h, the weighted mean given by equation (2) may differ from the proper value H_{0z}, both in magnitude and in the sign.

Babcock[2] cites two observational facts in support of his view: (1) No 'bias' is observed, which according to him is evidence against an influence of turbulence. Dr. Babcock writes that "According to Alfvén's arguments, the systematic effect of f and the way in which ρ and T are coupled with H should provide a large bias . . .". This is erroneous. Alfvén has never drawn this conclusion, nor has Babcock given any arguments for it. Further, according to Lehnert[3] t can be shown, even under very general assumptions, that turbulence will not give a bias.

(2) The Hale polarity law of bipolar sunspots is preserved down to very low magnetic fields. This is very interesting, but as the investigation from which this result is quoted is unpublished, it is impossible to discuss it. In view of the fact that this argument—if valid—is the only existing support for Babcock's sign and magnitude of the solar magnetic field, it is highly desirable that the details should be worked out and published, so that it may be possible to judge whether the conclusion is convincing or not.

The final verdict, whether Babcock's interpretation can be upheld or not, can only be given after a rigorous theory of the magnetic effects of granulation and their influence on the solar spectrum has been provided. No real attempt to develop such a theory has yet been published.

Direct Measurement of Long-Range van der Waals Forces

ACCORDING to the current theory of the stability of colloids, there exists a universal force of attraction between any two particles which has its origin in the summation of the London dispersion forces between atoms in the two bodies. Although the force between colloid particles is too small to be measured directly, that between macroscopic bodies is just measurable. For example, the theoretical force, F, between two plane parallel plates separated by a gap, d, is given by[1–3]:

$$F \approx A/d^3 \quad (1)$$

if d is less than about 100 A., or

$$F \approx B/d^4 \quad (2)$$

if d is greater than about 2000 A. A and B are force constants which can be calculated. As the theoretical value of B for glass (calculated from the expression given by Lifshitz[3]) is about $1{\cdot}4 \times 10^{-19}$ erg cm., the force at a spacing of 1μ (10^{-4} cm.) should be about $1{\cdot}4 \times 10^{-3}$ dyne per cm.^{2} (that is, 1·4 μgm.).

Two previous attempts which have been made to verify the magnitude of this force experimentally have given highly discrepant results. Derjaguin and Abricossova[4], using an electronically balanced knife-edge microbalance, obtained for quartz over the range 0·1–1μ results which correspond to $B \approx 1 - 2 \times 10^{-19}$ erg cm. Independently, Overbeek and Sparnaay[5] used a method in which the force between parallel glass plates, separated by 0·7–1·5μ, produced a small measured deflexion of a spring. These authors observed a force of 2 dynes at 1μ and their results were represented by equation (1) with $A = 3{\cdot}8 \times 10^{-11}$ erg. If their results were interpreted according to equation (2), the value of B would be 2×10^{-16} erg cm.

We have now carried out a new series of measurements with an apparatus similar in principle to that of Overbeek and Sparnaay but of improved sensitivity. The results of many reproducible experiments, in which the force between glass plates (optically flat to within 300 A.) was determined over the range 0·7–1μ, indicate that the force at a separation of 1μ is 1·2 (± 0·4) × 10^{-8} dyne per cm.^{2}, and the index of d is 3·9 ± 0·3. Hence, the value of B in equation (2) is 1·2 (± 0·4) × 10^{-19} erg cm.

The theory of the dispersion forces at large distances is therefore confirmed, in full agreement with the results of Derjaguin and Abricossova. In preliminary observations we also observed large forces similar to those reported by Overbeek and Sparnaay; these disappeared on application of a high-frequency discharge or when water-vapour was admitted to the apparatus. These observations add support to the suggestion made by Derjaguin and Abricossova that such forces originate from mosaic electrostatic charges.

Details of this work will be published elsewhere.

A General Expression for Intermolecular Potentials

A SYSTEMATIC project for the evaluation of virial coefficients (second, third and fourth) by automatic computation has been in operation on the *EDSAC* (Cambridge): tabulated results and mathematical procedures will be given elsewhere. This investigation, however, gave rise to the consideration of a related problem to which the following interesting solution has been found.

In the estimations of intermolecular potentials of spherical molecules to fit observed virial coefficients and related properties, there are a few well-known investigations[1] in which different expressions with two or three adjustable parameters have been tested and advocated. However, it appears desirable, in general, and particularly with respect to the present automatic calculations, to introduce a new expression which has an unlimited number of adjustable constants such as the coefficients of a power series. Such an expression should enable one to make further progress than by the trial of miscellaneous expressions: the agreement for any expression of tabulated functions with two or three parameters must presumably be limited and would be weakened by further improvement and extension of experimental data. This attempt at a systematic procedure seemed to be specially desirable for the most useful organization of the numerical results in the above investigation.

A few different types of expression were examined and the following was selected:

$$U(r) = \frac{4\varepsilon}{(r^2 + B^2)^3} \sum_{i=0} C_{2i} \left\{r^{2i} \exp A(1 - r^2) - 1\right\} \quad (1)$$

The intermolecular distance r is to be measured so that the potential $U(1)$ at unity is zero. The constants A and B^2 are to be assigned values about 4 and 1/10, but the constants C_{2i} are to be adjusted to fit experimental or fundamental theoretical data, and their free choice makes the expression dependent on a complete system of functions. The 4 and 1/10 choice has the surprising property that with $C_0 = 1$ and other $C_{2i} = 0$, the function is practically indistinguishable from the Lennard-Jones (12–6) potential,

$$V(r) = 4\varepsilon \left(\frac{1}{r^{12}} - \frac{1}{r^6}\right) \quad (2)$$

This degree of agreement had not been thought possible and is very gratifying, since the use of U provides thus a first term which is probably nearly as good as possible for a two-parameter expression while still permitting unlimited further adjustment.

Table 1

r	$U(r)/4\varepsilon$	
	Potential (1) with $C_0=1·0$; $C_{2i}=0$ ($i>0$)	(12–6) potential
0·80	7·948	10·737
0·90	1·511	1·659
0·94	0·623	0·652
0·98	0·144	0·146
1·00	0·000	0·000
1·02	−0·101	−0·099
1·06	−0·213	−0·208
1·10	−0·253	−0·246
1·12 (min.)	−0·257	−0·250
1·16	−0·248	−0·242
1·2	−0·227	−0·223
1·4	−0·112	−0·115
1·6	−0·053	−0·056
2·0	−0·015	−0·015
>2·0	Identical	

It does not appear likely that any powerful systematic way for evaluating C_0, C_2, C_4 from experimental data will be found. Their estimation will have to depend on solid-state and viscosity data as well as on the virial coefficients. However, some procedure of successive adjustment of the C_{2i} appears to offer for the first time a systematic way of summarizing the implications of the experimental data. It may also be hoped that this systematization of approach might be of some use in the selection of most effective experimental measurements.

In the work just performed on the *EDSAC*, the second, third and fourth virial coefficients for the basic potential with ($C_2 = C_4 = \ldots = 0$) and for two others with ($C_6 = C_8 = \ldots = 0$) have been calculated. Linear combinations of these can then be examined by means of the tabulated results to estimate the best functions to fit experimental data. It may be of interest to note that the calculation depended neither on the analytical form of the potential nor on numerical integration. It was based on an expansion of $\exp(-U/kT) - 1$ in terms of functions of the type $\exp(-ar^2)$. Practically all the organization and arithmetic of the evaluations were performed by the machine.

Thermal Expansion Coefficients for Uranium Boride and β-Uranium Silicide

THE thermal expansion coefficients for uranium boride (UB_2) and β-uranium silicide (USi_2) have been determined by X-ray powder methods with a high-temperature camera. The mean values for the expansion coefficients between room temperature and 205° C. for different directions in the lattice are summarized in Table 1.

Table 1. THERMAL EXPANSION COEFFICIENT (PER DEG C), MEAN VALUE BETWEEN 20° C AND 205° C.

Compound	Thermal expansion coefficient	Direction in the lattice
UB_2	9×10^{-6}	*a*-axis
	8	*c*-axis
	6	U–B bond direction
β-USi_2	57	*a*-axis
	−26	*c*-axis
	16	U–Si bond direction

These two compounds were selected because of their formally identical crystal structures. They both belong to space group $C\ 6/\tilde{m}\,m\,m$ and are of the AlB_2-type (C 32)[1–3]. The uranium atoms are situated in the 000 position of the simple hexagonal cell, whereas the non-metal atoms are situated in the $\frac{1}{3}\frac{2}{3}\frac{1}{2}$ and $\frac{2}{3}\frac{1}{3}\frac{1}{2}$ position. The structure may be regarded as formed by plane hexagonal sheets of uranium atoms (A) and plane hexagonal networks (H) of boron or silicon atoms. The sequence of the sheets in the [001] direction is $AHAHAH$ ..... The lattice constants and the interatomic distances for the two compounds are summarized in Table 2. MeB_2-lattices have also been discussed from several aspects by Post *et al.*[4].

Table 2 LATTICE PARAMETERS AND BOND-LENGTHS FOR UB_2 AND β-USI_2 (IN A.)

Compound	Lattice parameters	Distance U–U		Distance U–B (or U–Si)	Distance B–B (or Si–Si, network H)
		In sheet (A)	Between sheets (A)		
UB_2	$a=3{\cdot}136$ $c=3{\cdot}988$	3·14	3·99	2·69	1·81
β-USi_2	$a=3{\cdot}85$ $c=4{\cdot}06$	3·85	4·06	3·01	2·22

A study of the bond-lengths shows that, although uranium boride and β-uranium silicide are isostructural and formed by the same metal atom, several fundamental differences exist which depend on the difference in radius between the boron and the silicon atoms. If the small boron atom (r_B = 0·86 A.) is taken up between the hexagonal uranium sheets, the distance U–U between the sheets of 3·14 A. is still within the limits for a metallic bond to be formed between the uranium atoms. (In the α-, β-, γ-phases of uranium the distances between nearest neighbours of metal atoms varies within the limits 2·75–3·30 A.) The silicon atom (r_{Si} = 1·17 A.), however, is accommodated between the metal sheets only if the uranium atoms are considerably separated (distance U–U = 3·85 A. in the sheets). There is thus probably no bond-formation between the uranium atoms in the metallic sheets of β-uranium silicide.

In the hexagonal networks (H) of non-metal atoms in uranium boride, the boron atoms have a separation of 1·81 A., which is 5 per cent larger than the sum of the atomic radii. In β-uranium silicide, however, the silicon–silicon distance of 2·22 A. is 5 per cent smaller than the sum of the atomic radii.

The U–B distance in uranium boride is 11 per cent bigger than $r_U + r_B$ and the U–Si distance in β-uranium silicide is 10 per cent bigger than $r_U + r_{Si}$, using 1·50 A. as the radius for the uranium atom.

The difference in the nature of the bonds in the isostructural compounds uranium boride and β-uranium silicide is clearly reflected in the thermal expansion coefficients for the two lattices. The lattice of uranium boride, with a radius ratio of $r_B/r_U = 0{\cdot}57$, expands uniformly. The coefficient of thermal expansion is nearly equal in different bond directions, indicating that the lattice is held together by bonds of the same nature. It is thus conceivable that the atoms in the same uranium sheets (A) are held together by metallic bonds, whereas the distance between the uranium atoms in different sheets is too big (3·98 A.) to permit any direct bond formation. The sheets are held together by the boron atoms, forming uranium–boron–uranium bonds in addition to the boron–boron bonds in the networks (H). A possible way might be that electrons from the boron atoms are taken up by the unfilled 6*d*-levels of the uranium atoms and the lattice stabilized by electron oscillation in different bond directions.

For β-uranium silicide the radius ratio r_{Si}/r_U is 0·78. The extraordinarily big thermal expansion of the uranium sheets (the direction of the *a*-axis) probably depends on the facts that no direct binding forces exist between the uranium atoms in the sheets and that the hexagonal networks of silicon atoms parallel to the sheets are considerably 'compressed'. The lattice is held together by silicon–silicon and uranium–silicon–uranium bonds. The negative expansion coefficient between the uranium sheets (*c*-axis) is remarkable and shows that the type of bonding in the β-uranium silicide lattice is different from the bonding in the uranium boride lattice.

Other studies of the thermal expansion coefficients for pairs of isostructural compounds are planned. Uranium boride and chromium boride[3] form, for example, a pair of isostructural compounds where the size of the metal atom is varied for the same non-metal atom. The isostructural pair uranium silicide[2] and iron boride[3] might show other aspects of the nature of the bonds within silicides and borides.

Symbols for Lattice Disorders

MODERN concepts of crystal physics and chemistry have made it necessary that appropriate symbols should be evolved to designate all kinds of disorders occurring in a crystal lattice. Though several sets of symbols are in use, they are not universally accepted and they are not self-explanatory; indeed, authors often include a glossary of their symbols, which shows that they do not expect the reader to understand or recognize their symbols. It is never sure whether the sign and number of electric charges in the symbol are meant to express the true charge of the particle at a given site or the difference in charge caused by the disturbance.

The choice of an appropriate symbolism is important for the development of a young branch of science. In the present case, I think it should fulfil the following conditions: (1) It should state which particle is really there at the site in question, indicating its true electric charge. (2) It should state what kind of site is in question: that of a normal lattice cation, or a lattice anion, or an interlattice site. No other legitimate site exists in an ideal crystal, therefore it is misleading to speak, for example, of a vacant bromine *atom* site in a silver bromide crystal where only bromine ions are expected to exist in the ideal case. (3) It should state the difference in electric charge at the given site caused by the disturbance as against the undisturbed ideal lattice, taking care, however, that this difference in charge should not get mixed up with the effective charge of the particle. (4) Symbols which have been more or less generally accepted hitherto should be retained so far as possible, to minimize confusion in the interim period. Thus the symbol $\square$ could be retained for a vacant site, the symbol $\bigcirc$ for an interlattice site, with suffixes if necessary when more than one kind of interlattice site can occur. Probably a strained lattice site around an interlattice atom would deserve a separate symbol for itself, but this problem is generally neglected. The symbol $\ominus$ should, of course, remain for an electron, but the converse symbol $\oplus$ should be dropped altogether, because no positrons are to be expected and the 'charge difference' of + 1 against the ideal lattice is simply designated by +, just as a difference of + 2 is indicated by + +.

Several systems of symbols conform with the conditions set out above. I do not venture to decide in favour of any one of them in particular; however, I will direct attention to some which I regard as acceptable. All have in common that the first three points demanded above are provided for at well-defined parts of the aggregate symbol. Further, the whole symbol might be enclosed in rectangular brackets with the real particle first, the site of the particle next and the difference of charge caused by the disturbance at the right higher corner of the end-bracket. The following lattice disorders could be symbolized by one of the four subsequent symbols, taking, for example, a silver bromide lattice:

Vacancy at the site of a silver ion:

$$[\square, Ag^{+}]^{-}; \quad [\square; Ag^{+}]^{-}; \quad [\square, \mathbf{Ag}^{+}]^{-}; \quad [\square/Ag^{+}]^{-}$$

Vacancy at the site of a bromine ion:

$$[\square, Br^{-}]^{+}; \quad [\square; Br^{-}]^{+}; \quad [\square, \mathbf{Br}^{-}]^{+}; \quad [\square/Br^{-}]^{+}$$

An electron at the site of a bromine ion:

$$[\ominus, Br^{-}]; \quad [\ominus, Br^{-}]; \quad [\ominus, \mathbf{Br}^{-}]; \quad [\ominus/Br^{-}]$$

A silver ion at an interlattice site:

$$[Ag^{+}, \bigcirc]^{+}; \quad [Ag^{+}; \bigcirc]^{+}; \quad [Ag^{+}, \boldsymbol{\bigcirc}]^{+}; \quad [Ag^{+}/\bigcirc]^{+}$$

A sulphide ion at the site of a bromine ion:

$$[S^{--}, Br^{-}]^{-}; \quad [S^{--}; Br^{-}]^{-}; \quad [S^{--}, \mathbf{Br}^{-}]^{-}; \quad [S^{--}/Br^{-}]^{-}$$

A cadmium ion at the site of a silver ion:

$$[Cd^{++}, Ag^{+}]^{+}; \quad [Cd^{++}; Ag^{+}]^{+}; \quad [Cd^{++}, \mathbf{Ag}^{+}]^{+}; \quad [Cd^{++}/Ag^{+}]^{+}$$

Symbols for other disturbances follow naturally from this system. An electron in the conductive band would be simply represented by the symbol of the electron, $\ominus$; an ion at its own lattice site by its symbol in brackets. Thus the sequence of photoionization of a bromine ion and the capture of the freed electron from the conductivity band by a silver ion could be written as:

$$[Br^{-}] + h\nu \rightarrow [Br, Br^{-}]^{+} + \ominus \text{ and }$$
$$\ominus + [Ag^{+}] \rightarrow [Ag, Ag^{+}]^{-}$$

The dislocation of a silver ion into an interlattice site or its return therefrom into its vacancy would read:

$$[Ag^{+}] \rightleftarrows [Ag^{+}, \bigcirc]^{+} + [\square, Ag^{+}]^{-}$$

I think it is high time that specialists on these problems should attempt to obtain international agreement on a set of symbols that will be universally accepted and as clear and self-explanatory as compatible with the complexity of the situation.

Spectrophotometry of Granulated Materials, with Particular Reference to Blood Corpuscles

Although expressions have been developed[1,2] for the interpretation of spectrophotometric measurements on granulated materials, little consideration has been paid to the effects of scattering of the incident radiation. Measurements may be made with varying amounts of the scattered radiation received.

(1) *No scattered radiation received* (this is ideally achieved using a parallel beam of radiation with the detecting device subtending zero angle at the suspension). The transmission of a parallel beam through a layer of disks may be calculated by considering the interference between the wave-fronts transmitted by the particle and the medium. If a suspension contains n disk-like particles per c.c. having a thickness t parallel to the beam and an area s perpendicular to the beam, and if the particles are absorbing, having an extinction coefficient E, then the amplitude of the wave emerging from the particle will be reduced by a factor $10^{-Et/2}$ and its phase will differ from that of the remainder of the beam by some angle φ. Considering radiation $A \sin \omega t$ incident on unit area, the wave emerging from a layer of thickness δl will be:

$$A(1 - ns\delta l) \sin \omega t + A\, ns\delta l\, 10^{-Et/2} \sin (\omega t \pm \varphi)$$

and the resultant intensity will be given by the sum of the squares of the coefficients of $\sin \omega t$ and $\cos \omega t$: neglecting terms in $(\delta l)^2$, and integrating over a finite thickness l, the optical density d of the suspension is:

$$d = 2 \log_{10} e.\, nsl\, (1 - 10^{-Et/2} \cos \varphi) \qquad (1)$$

For transparent particles ($Et \rightarrow 0$), the optical density will therefore be a maximum when $\varphi = \pi$, that is, when there is destructive interference between the radiation transmitted through and around the particle: for opaque disks (large Et) no interference can occur and the optical density is reduced. An absorption band will therefore be evident as a decrease in optical density—the exact reverse of normal behaviour.

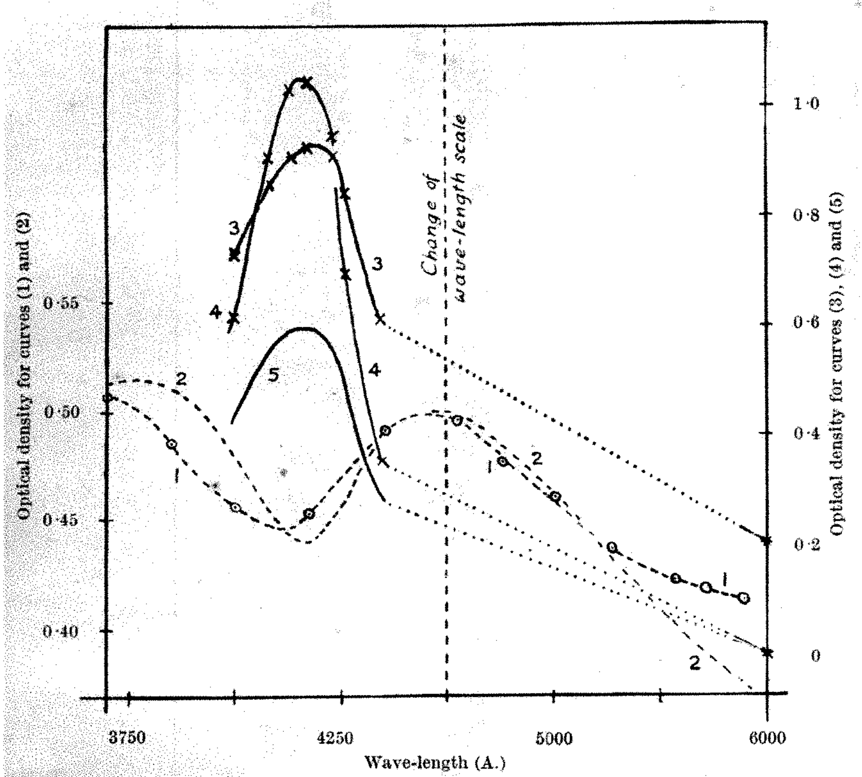

Fig. 1

Blood corpuscles in normal saline are approximately disk-shaped, and calculation shows that $\varphi = \pi$ at a wave-length of 3600 A.—near the γ- or Soret band: measurements were therefore made on a suspension of corpuscles which had all settled to show a circular section to the beam of radiation (the incident and measured beams were parallel[3] to within 1°). The results (curve 1) do show the Soret band inverted, but do not conform to equation (1); a closer approximation to the shape of the corpuscle, namely, two contiguous concentric disks each of area $\frac{1}{2}s$ with the outer ring twice the thickness of the inner disk, leads to an analogous equation which gives curve 2 in fair agreement with experiment.

(2) *All scattered radiation received.* The intensity transmitted through a layer of oriented disks is now the sum of the intensities transmitted through the disks and through the intervening spaces. This leads to an expression[1,2] for the optical density:

$$d_{\text{suspension}} = \log_{10}e.\ nsl\,(1 - 10^{-Et}) \qquad (2)$$

whereas if the absorbing material were uniformly dispersed in the same volume, then the optical density of the solution would be

$$d_{\text{sol.}} = n.\ s.\ t.\ El \qquad (3)$$

These equations indicate that the peak of an absorption band will be depressed when measured on a suspension.

Measurements have been made on oriented blood corpuscles in saline using a converging beam with $F/1{\cdot}5$ lenses above and below the cell, and with the base of the cell ground on both sides so that some of the scattered radiation is collected. (Similar measurements on the alga *Chlorella* have recently been reported[4].) Curve 3 shows a typical absorption curve for a suspension with measurements (curve 4) on the same sample after hæmolysis. Calculation of the optical density from equation (2) gives curve 5. The difference in optical density between curves 3 and 5 may be ascribed to the radiation scattered backwards by the corpuscles; this difference is not, however, independent of wave-length or absorption. The displacement of the maximum of the corpuscular suspension may be at least partly explained by the anomalous dispersion around an intense absorption band[5].

(3) *Some scattered radiation received.* In this intermediate case the minimum of curve 1 and the depressed maximum of curve 3 will tend to cancel out: this would explain the failure of early measurements[6] on corpuscular blood to show the Soret band. This effect is of importance if measurements on powders in disks of potassium bromide, etc., are to be comparable to measurements on a uniform specimen. As much scattered radiation as possible should be collected; and the powder should be ground so finely that the absorption of a single particle is small ($Et \to 0$), when equations (2) and (3) become identical.

'Clean-up' of Radioactive Gases used for Surface Studies

THE gradual decrease of the gas pressure in discharge tubes due to the capture of the gas on the walls and on the electrodes of the tube (electrical clean-up) has been the subject of numerous investigations (for reviews, see refs. 1 and 2). Use of radioactive gas for these studies has several advantages as shown, for example, by Harris and Hawkins[3], who used krypton-85 in measuring gas clean-up rates in switching devices for radar duplexers.

We have now found that the 'clean-up' of radioactive gases can be used as a valuable tool for surface studies because the quantity of the gas cleaned up into the surface, for example, of a glass plate depends to a large extent on the quality of the surface and is affected by the presence of traces of other substances on the surface.

In our experiments radon or radioactive xenon-131 was 'cleaned up' into the surface of a glass plate by a high-frequency discharge produced in a cell consisting of the glass plate and a brass plate held apart by a ring-shaped rubber spacer 2 mm. thick. This cell could be filled with air containing several microcuries of radon or xenon at a pressure of 15–20 mm. mercury. Gas discharge was maintained in the cell for about 30 sec. by simply connecting a plate electrode attached to the outside of the glass wall to the coil of a high-frequency vacuum tester.

The discharge causes a fraction of the radioactive gas to become embedded in the glass plate, and its areal distribution can be checked by taking autoradiographs. Treating the surface of the glass plate with water, organic solvents or concentrated sulphuric acid does not remove an appreciable fraction of the gas from the surface. It is, of course, partially removed by concentrated alkali and completely liberated by hydrofluoric acid. At normal temperature the 'effective' half-life of the cleaned-up radon was found to be about 3 days because of its partial escape by diffusion. Heating the plate for 10 min. to 310° C. caused 60 per cent of the radon activity to escape. The depth of the glass layer in which atoms of radon are embedded can be estimated from recoil phenomena accompanying its alpha-decay. On bringing a glass surface (*A*) with the cleaned-up radon in vacuum into contact for about four hours with a second glass plate *B*, 45 per cent of the equilibrium amount of the short-lived products of radon are found on the plate *B*. Such a high transfer of the decay products by recoil is possible only when most of the atoms of radon are located within a distance from the surface which is small compared with the recoil range of the radium-A atoms in the glass, which is of the order of 200 A.

Areal concentration of the cleaned-up gas is fairly homogeneous over the whole glass surface cleaned chemically, for example, with sulphuric acid potassium permanganate solution, rinsed with re-distilled water and dried. Traces of impurities or various substances such as grease, solid hydrocarbons or polymers covering the surface in the form of thin films inhibit, according to their thickness partially or completely, the ability of the surface to clean-up radioactive gas, and their presence is easily revealed by autoradiographs. Disturbing the surface layer of the glass by grinding it with fine 'Carborundum' powder or by treating it with hydrofluoric acid also modifies the ability of the surface to clean-up gas. Typical examples of these effects are demonstrated in Fig. 1. This is an autoradiograph of a glass surface on which, previous to radon clean-up, a drop of 2×10^{-3} *M* solution of stearic acid in petroleum ether had been evaporated and a strip of its surface about 2 mm. wide was ground with 'Carborundum' powder.

Stepwise deposition of odd numbers of monomolecular layers of calcium stearate on the glass surface (Langmuir–Blodgett technique) resulted in clean-up radiographs with steps of decreasing density corresponding to various thicknesses of the deposited film. A single monolayer of stearate of about 25 A. thickness is sufficient to cause a distinct decrease in the ability of the surface to clean-up radioactive gas. This can be understood on the basis of a mechanical type of clean-up mechanism: the film prevents low-energy inert gas ions, accelerated during the discharge towards the glass surface, from reaching it and from being occluded there.

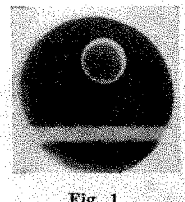

Fig. 1

Clean-up can thus be used as a very simple means for the study of deposited monomolecular films, and its use for evaporated metal films also seems promising. This method can also be used for the preparation of samples of radioactive gases when measuring their soft radiation and for obtaining a very convenient radon source for demonstrating and investigating the alpha recoil phenomena.

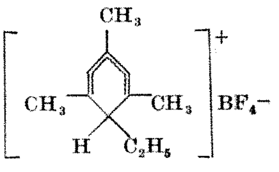
Isolation of the Stable Boron Trifluoride-ethylfluoride and Boron Trifluoride-formylfluoride Complexes of the Methylbenzenes : Mechanism of the Friedel–Crafts Reactions

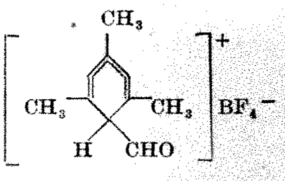
IN an earlier communication[1] we have reported the isolation of the stable boron trifluoride–hydrogen fluoride complexes of the methylbenzenes and described the carbonium ion salt (or σ-complex) structure of these compounds.

We have now succeeded in isolating the stable complexes from the methylbenzenes with ethylfluoride–boron trifluoride and formylfluoride–boron trifluoride. On dissolving equimolecular quantities of ethylfluoride in toluene, *m*-xylene and mesitylene at − 30° to − 80° a homogeneous clear solution is obtained. Introduction of boron trifluoride into the solution leads to the separation of a bright-coloured lower phase, and by continuing the addition of boron trifluoride the quantity of this phase is increased. The solution removes one mole of boron trifluoride, after which we obtain again a homogeneous bright-coloured substance with a measurable melting point and a very significant electric conductivity.

Formylfluoride is only partly soluble in the methylbenzenes. The equimolecular methylbenzene–formylfluoride mixture becomes immediately brightly coloured on introduction of boron trifluoride and becomes homogeneous by losing one mole.

The 1 : 1 : 1 molecular complexes can be formulated, for example, in the case of mesitylene, in the following manner :





In this case we have been able to isolate the intermediate complexes of the Friedel–Crafts ethylation and formylation of aromatic compounds.

By the slow thermal decomposition of the complexes the homogeneous substance separates again into two phases: an upper organic phase, which was identified after washing and distillation as an ethyl methylbenzene and formyl methylbenzene respectively, with nearly quantitative yield; and a lower phase, which contains the stoichiometrical quantity of hydrogen fluoride with a negligible quantity of the dissolved aromatic. By the action of the hydrogen fluoride on the aldehyde produced in the formylation reaction some tarry material is formed, probably by the polymerization of the aldehyde.

The properties of the isolated $ArHC_2H_5^+BF_4^-$ and $ArHCHO^+BF_4^-$ complexes are given in Table I.

Table 1

$ArHC_2H_5^+BF_4^-$

Ar	Melting point (°C.)	$\varkappa(\Omega^{-1}.cm.^{-1})$	Colour
$CH_3C_6H_5$	−80	$0{\cdot}2 \times 10^{-2}$	Yellow
$m(CH_3)_2C_6H_4$	−75	$0{\cdot}1 \times 10^{-2}$	Red
$s(CH_3)_3C_6H_3$	−15	$0{\cdot}2 \times 10^{-2}$	Orange

$ArHCHO^+BF_4^-$

Ar	Melting point (°C.)	$\varkappa(\Omega^{-1}.cm.^{-1})$	Colour
$CH_3C_6H_5$	−70	$0{\cdot}4 \times 10^{-2}$	Red
$m(CH_3)_2C_6H_4$	−52	$0{\cdot}5 \times 10^{-2}$	Cherry-red
$s(CH_3)_3C_6H_3$	−16	$0{\cdot}7 \times 10^{-2}$	Red
$as(CH_3)_4C_6H_2$	−10	$0{\cdot}7 \times 10^{-2}$	Cerise

As a result of the foregoing investigations, we have been able to investigate the ethylation and formylation of a methylbenzene, for example, toluene with the boron trifluoride-catalysed action of ethylfluoride and formylfluoride, so to say in elementary steps.

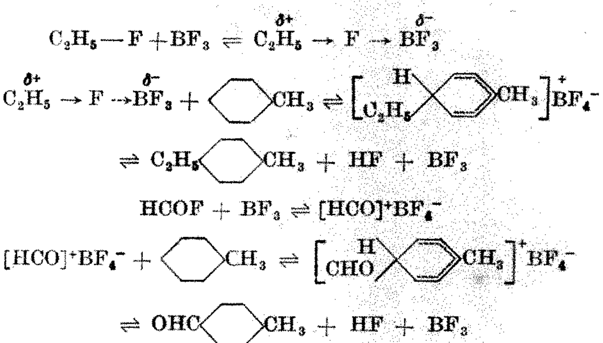
In earlier work[2], we have demonstrated that ethylfluoride forms at low temperature a 1 : 1 molecular complex with boron trifluoride. This molecular complex has at above − 95° a specific conductivity of $\varkappa = 0{\cdot}5 \times 10^{-6}\ \Omega^{-1}.\ cm.^{-1}$ in the melted state. From this low conductivity value it is evident that the complex has mainly a polarized covalent character and can be only to a very slight degree ionized. This is in full agreement with H. C. Brown's[3] suggestion of the first step of the alkylation reaction of aromatics by the aluminium halide-catalysed reaction with ethyl halides.

Also in earlier work[4] we have demonstrated that formylfluoride forms at low temperature a 1 : 1 molecular complex with boron trifluoride. This complex has at − 110° a specific conductivity of $\varkappa = 0{\cdot}1 \times 10^{-2}\ \Omega^{-1}.\ cm.^{-1}$ in the melted state. From this high conductivity value it is evident that the complex has a carboxonium ion salt structure similar to the acetyl tetrafluoroborate isolated earlier by F. Seel[5].

The ethyl borofluoride complex which we have prepared at a low temperature is a colourless compound which melts with decomposition at about − 95° and has—as mentioned—a very small specific conductivity. If we add now—also at low temperature—an equimolecular quantity of cold toluene to the ethyl borofluoride complex, the colour is changed immediately to bright yellow, the specific conductivity increases to a value of $\varkappa = 0{\cdot}2 \times 10^{-2}\ \Omega^{-1}.\ cm.^{-1}$ and we obtain the homogeneous well-identified complex as in the case of the one-step complex formation described earlier in this communication.

In the case of the formyl tetrafluoroborate the complex we have prepared is a colourless compound, which decomposes at about − 110°. If we add now, also at low temperature, an equimolecular quantity of cold toluene to the formyl tetrafluoroborate complex, the colour is changed immediately to bright red. The specific conductivity increases to $\varkappa = 0{\cdot}4 \times 10^{-2}\ \Omega^{-1}.\ cm.^{-1}$ and we obtain the homogeneous well-identified complex as in the case of the one-step complex formation between toluene, formylfluoride and boron trifluoride.

We formulate, on the ground of the direct preparative proofs of the isolation of the two intermediate complexes, the electrophilic alkylation and formylation mechanism in the following manner (for the sake of simplicity we indicate only the formation of the *para* product :



$C_2H_5—F + BF_3 \rightleftharpoons \overset{\delta+}{C_2H_5} \rightarrow F \rightarrow \overset{\delta-}{BF_3}$
$\overset{\delta+}{C_2H_5} \rightarrow F \rightarrow \overset{\delta-}{BF_3}$ + CH₃ ⇌ H C₂H₅ CH₃ + BF₄⁻
⇌ C₂H₅ CH₃ + HF + BF₃
$HCOF + BF_3 \rightleftharpoons [HCO]^+BF_4^-$
$[HCO]^+BF_4^-$ + CH₃ ⇌ H CHO CH₃ + BF₄⁻
⇌ OHC CH₃ + HF + BF₃

We believe that the isolation of the onium-ion salt intermediate complexes makes possible a better understanding in general of electrophilic aromatic substitutions.

Super-Acid Formation in the Pyridine–Acetic Acid System

A STUDY of the physico-chemical properties of mixtures of pyridine and acetic acid in all proportions ranging from 0 to 100 per cent by various workers and very recently by us[1] showed that the equivalent conductivity, viscosity, contraction in volume, and refractive index exhibited in each case a maximum at a composition of 83 mol. per cent of acetic acid. Previous workers ascribed the maxima to the formation of a complex at that composition. A consideration of the dynamics of ionic atmospheres in relation to the effect of an electrolyte dissociating into ions on the viscosity of a solution and other factors (*loc. cit.*) led us to assume that no compound-formation occurs, and that, instead, at that composition acetic acid attains maximum ionization. At least 17 mol. per cent of pyridine is necessary for complete ionization of acetic acid in pyridine.

The hydrogen ions thus obtained from the acetic acid dissociation must be assumed[2,3] to exist as pyridinium ions involving one pyridine molecule for each hydrogen ion. But when the number of pyridine molecules is insufficient to form pyridinium ions some free hydrogen ions have to be assumed to exist, and necessarily so at 83 mol. per cent composition of acetic acid, where the dissociation is complete. It is to be expected that a study of *p*H at different compositions of the mixture starting from 0 to 100 per

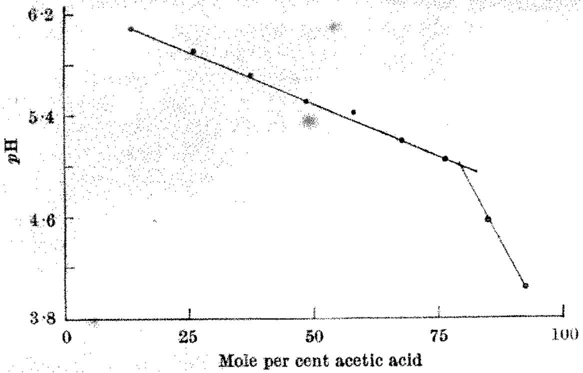

Fig. 1. Graph showing pH of pyridine–acetic acid system

cent pyridine should indicate a minimum at 17 mol. per cent of pyridine, at which composition acetic acid dissociates completely.

We have studied the pH of mixtures of pyridine and acetic acid and the results are represented graphically in Fig. 1. The measurements were made with a glass electrode in conjunction with a saturated dip-type calomel electrode in a Morton's glass electrode assembly unit with a Cambridge pH meter. The values obtained were quite reproducible. Surprisingly, the pH behaviour between 83 and 100 mol. per cent of acetic acid is quite the reverse of our expectation. In this region, for conductance as well as pH, the same downward trend makes it inevitable that the free hydrogen ions left over, due to an insufficient number of pyridine molecules to form pyridinium ions, must be assumed to have attached themselves to undissociated acetic acid molecules, forming $CH_3COOH_2^+$ ions exhibiting the well-known super-acid behaviour[4-6]. The pH curve thus proves the existence of undissociated molecules of acetic acid in the region 83–100 per cent acetic acid, as well as super-acid formation.

Structure of a Grass Pollen Flavonoid Glycoside

A flavonoid glycoside, dactylin, was found to occur in pollens of timothy and orchard grass in 1931 by Moore and Moore[1]. Until this present study, there existed no complete structural data on dactylin. An abstract by Johnson *et al.*[2] indicated that dactylin was not chromatographically similar to simultaneously processed *iso*quercitrin, quercitrin and quercetin. They also report that spectrographically dactylin aglycon and quercetin, individually and mixed, have identical patterns in three solvent systems.

For the studies reported here[3], dactylin was re-isolated from timothy pollen. It was obtained as a light yellow solid from a 1955 crop of defatted pollen. It was readily recrystallized from water, and paper chromatography revealed only one spot in three solvent systems. The methoxyl content was 3·60 per cent, and the dactylin aglycon (obtained by 2 N sulphuric acid hydrolysis of dactylin) revealed 6·93 per cent methoxyl content. Infra-red and ultra-violet spectra and melting-point data suggested the aglycon to be impure *iso*rhamnetin. Acetylation of the aglycon gave 3,5,7,4′-tetra-acetoxy-3′-methoxy-flavone that had an infra-red spectrum identical in every respect with a known sample. On admixture with the known sample, no depression of melting point was observed. Methylation of the aglycon with diazomethane gave 3,7,3′,4′-tetramethoxy-5-hydroxy-flavone that also had an infra-red spectrum identical in every respect with a known sample. On admixture with a known sample, no depression of melting point was observed.

When dactylin was methylated with diazomethane and hydrolysed, 5,7,3′-trimethoxy-3,4′-dihydroxy-flavone was obtained that was identified by mixed melting point and identical infra-red spectrum with a known sample. The reference sample was kindly supplied by Dr. Richard Kuhn, of the Max Planck Institute for Medical Research. Therefore, the structure of dactylin was shown to be *iso*rhamnetin 3,4′-diglucoside and identical with the flavonoid glycoside isolated and characterized by Dr. Kuhn from the pollen of *Crocus* Sir John Bright[4].

Chromatographic Study of Jute α-Cellulose

A number of papers and communications have been published by different workers in recent years on the chromatographic study of jute α-cellulose, and conflicting views have been expressed regarding its association with different sugar residues. Sarkar *et al.*[1] consider the material to be entirely composed of glucosan, while Das and co-workers[2] contend that it is intimately associated with both xylose and arabinose residues. Adams and Bishop[3] believe that, in addition to these pentosans, jute α-cellulose contains uronic acid residue, the presence of which is yet to be confirmed by the chromatographic analysis.

Although Sarkar and others[1], and Adams and Bishop[3] have employed the same hydrolytic procedure of 72 per cent sulphuric acid, the failure of the former authors to detect pentoses in the hydrolysate appears to be due to interference caused by the presence of a large amount of glucose which has, however, been preferentially removed by the latter authors by the action of an enzyme preparation. Das *et al.*[2], and more recently Adams and Bishop[4], have applied a method of selective hydrolysis with formic acid to identify pentosans in jute α-cellulose, although Mazumdar and Sarkar[5], on using the same procedure, have failed to substantiate this observation.

It was noted, during the preliminary experiments carried out in this laboratory, that only glucose and xylose could be detected on the chromatogram of the jute α-cellulose hydrolysate obtained with the 72 per cent sulphuric acid method. The work described in

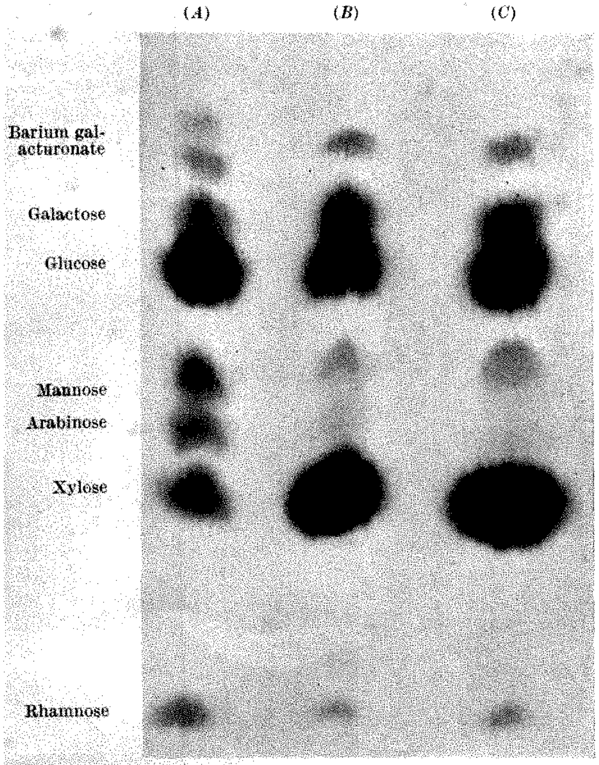

Fig. 1. Chromatogram with three successive runs of 56, 36 and 30 hr.: (*A*) reference sugars; (*B*) α-cellulose isolated by 9·5 per cent alkali; (*c*) α-cellulose isolated by 17·5 per cent alkali

this communication, however, has shown that on changing the hydrolytic procedure, that is, by using a dilute sulphuric acid solution instead of strong acid to effect only a partial hydrolysis, the conversion of glucosan to simple sugar is greatly restricted and, on following the technique of interrupted development of the chromatogram, it is possible to identify a number of associated sugars in addition to those already reported[2-4].

A small quantity of α-cellulose (0·5–2 gm.) is usually hydrolysed for the chromatographic analysis; but in the present investigation, a larger amount of the sample (10 gm.) was employed with the view of obtaining a more concentrated extract of associated sugar residues, particularly of those occurring in small proportions. Jute α-cellulose was prepared by treating the isolated chlorite holocellulose with sodium hydroxide solution under two different conditions, namely, (1) 17·5 per cent alkali at 20° C. according to the A.C.S. method and (2) 9·5 per cent alkali at room temperature. The sample was partially hydrolysed on heating with *N* sulphuric acid (200 c.c.) by immersing the reaction vessel in boiling water for 1 hr., when the material suffered a loss in weight of 4–6 per cent. The extract was further hydrolysed by refluxing for 6 hr., neutralized with barium carbonate to *p*H 5·6, concentrated at 35° C. to a small bulk and chromatographed on Whatman No. 1 filter paper with *n*-butanol – acetic acid – water (1 : 0·24 : 1) as the solvent, sugars being detected on spraying with aniline hydrogen phthalate. When the chromatogram was run at a stretch over a prolonged period (96–120 hr.) in order to effect separation of individual components, the spots of sugars occurring in small amounts became too faint to be detected with certainty by visual examination. On interrupting the flow of the chromatogram, that is, by subjecting the paper to three successive runs, initially for 56 hr. and then twice for 36 and 30 hr., sugars could be easily identified, although the shape of the spot suffered a considerable change from that obtained after a single run.

A typical chromatogram (Fig. 1) of the hydrolysate obtained from white jute α-cellulose, prepared by two different procedures, shows the presence of barium uronate, galactose, mannose and rhamnose in addition to glucose, xylose and arabinose already identified; the spot of arabinose is particularly faint in the case of the sample prepared with 17·5 per cent alkali. The hydrolysate from tossa jute α-cellulose also yielded a similar chromatogram and, from the size and intensity of the spots obtained, the material appeared to be associated with increased amounts of both xylose and arabinose. Individual sugars were isolated after separation on Whatman No. 3 *MM* filter paper and confirmed by measuring the respective R_F values, further confirmation of uronic acid being obtained from naphthoresorcinol and that of galactose from mucic acid tests. Jute α-cellulose, therefore, appears to be associated, irrespective of its method of isolation, with mannose in addition to the other sugars so far detected in the holocellulose fraction[6].

Rise of Serum Folic Acid-Levels after Injection of Vitamin B_{12} in Nutritional Macrocytic Anæmia

Although certain similarities between folic acid and vitamin B_{12} as agents involved in hæmopoiesis, nucleic acid synthesis and single-carbon transfers are well known, there is very little information on the manner in which these two chemically dissimilar vitamins affect each other. We wish to make a preliminary report of observations which show that the administration of vitamin B_{12} causes a rise in the serum folic acid-level in patients with nutritional macrocytic anæmia.

The total vitamin B_{12} content in the serum was determined by a modification of the microbiological (*Euglena*) method of Ross[1] using the extraction procedure of Shenoy and Ramasarma[2]; the folic acid content was determined microbiologically with *L. casei* as the test organism[3].

In some of the earlier cases of nutritional macrocytic anæmia treated with daily injections of 10 mgm. of folic acid, a definite increase in serum vitamin B_{12} concentration was noticed 24–72 hr. after commencement of therapy, whereas in others no significant changes could be seen. If this increase was due to mobilization of vitamin B_{12} from tissue stores, it is reasonable to expect a bigger rise in patients who have larger stores of vitamin B_{12}. In order to test this

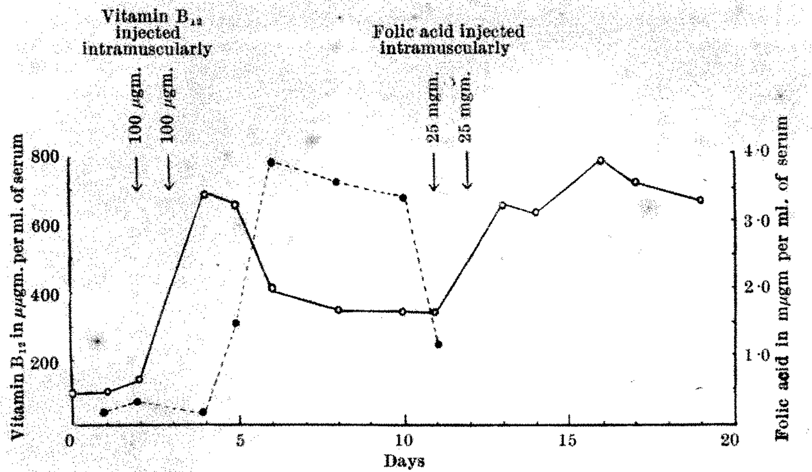

Fig. 1. Changes in serum concentrations after injections of vitamin B_{12} and folic acid in a patient with nutritional macrocytic] anæmia. ○——○, vitamin B_{12}; ●——●, folic acid

hypothesis and also to test the effect of parenteral vitamin B_{12} on serum folic acid-levels, the following general plan was adopted.

After a control period of five to nine days, each patient was given two intramuscular injections of 100 μgm. of vitamin B_{12} on consecutive days. Eight days later, he was given two intramuscular injections of 25 mgm. of folic acid on consecutive days and was kept under observation for a week or more. The results are summarized in Table 1, and a striking example is shown in Fig. 1.

The pretreatment values for serum folic acid were within the range 0·28–2·55 mμgm. per ml. However, these values increased several-fold after the administration of vitamin B_{12}, the peak-levels being usually reached within three to seven days. These results confirm the observations made by Nieweg *et al.*[4].

The initial concentrations of serum vitamin B_{12} in most of the patients were subnormal (less than 100 μμgm./ml.) or marginal. The injection of vitamin B_{12} caused a sudden rise in the serum-levels which, as can be expected, showed a rapid fall during the next three or four days. Thereafter the values declined slowly or remained practically constant. Of particular interest was the observation that, in every case studied, the trend of falling vitamin B_{12}-levels was reversed in 24–48 hr. after the injection of folic acid. In all cases the subsequent rise was sustained and of high statistical significance. The peak value was reached about the sixth day after injection of folic acid. The changes in the free B_{12} levels (not included in Table 1) were small and, therefore, the observed increases in the total vitamin B_{12} were obviously due to the combined vitamin, which is released only after digestion with papain.

Table 1. SUMMARY OF DATA ON SERUM FOLIC ACID AND VITAMIN B_{12} LEVELS IN 13 NUTRITIONAL MACROCYTIC ANÆMIA PATIENTS DURING TREATMENT

	Folic acid content (mμgm./ml.)		Vitamin B_{12} content (μμgm./ml.)	
	Before B_{12} injection (*a*)	After B_{12} injection (*b*)	Before folic acid injection (*c*)	After folic acid injection (*d*)
Range Average	0·28–2·55 0·94	1·37–5·85 2·87	180–598 414	269–978 662
Mean difference *t* *P*	1·93 6·4 < 0·1 per cent (highly significant)		248* 6·5* < 0·1 per cent (highly significant)	

a, Mean of values for three consecutive days; *b*, mean of six values during 8 days; *c*, mean of three values during 4 days; *d*, mean of five values during 7 days.

* In another series of nine patients in whom only the serum B_{12} concentrations were studied, the mean difference of 123 μμgm./ml. was found to be highly significant ($t = 5·7$, $P < 0·1$ per cent).

Although the observed rises could be explained on the basis of increased absorption from the gut or decreased urinary excretion, the fact that folic acid elicited a more striking increase of serum B_{12} in those patients whose B_{12} stores were augmented by prior medication suggests that its action is one of mobilization of vitamin B_{12} from the body stores. Such a conclusion is also compatible with Vilter's theory of 'mass action effect'[5], and the numerous clinical observations on the use of folic acid in the treatment of pernicious anæmia[6] as well as the recent findings by Harris[7].

A detailed report of this work will be sent to the *Indian Journal of Medical Sciences.*

Effects of Chlorpromazine and Dinitrocresol

THE observations of Berger, Strecker and Waelsch[1] on the action of chlorpromazine on oxidative phosphorylation of mitochondria prompt us to report that chlorpromazine has been observed to potentiate the action of 2,4-dinitro*ortho*cresol (DNC) in white mice. Mice weighing 16–21 gm. were given this substance subcutaneously, followed immediately by chlorpromazine hydrochloride intraperitoneally. The results obtained (at a room temperature of 25° C.) are as follow:

Dose	No. of animals	No. dead after 24 hr.
20 mgm./kgm. DNC	10	1
20 mgm./kgm. DNC + 5 mgm./kgm. chlorpromazine	10	6
25 mgm./kgm. DNC	10	6
25 mgm./kgm. DNC + 5 mgm./kgm. chlorpromazine	10	8
25 mgm./kgm. DNC + 10 mgm./kgm. chlorpromazine	10	9
5 mgm./kgm. chlorpromazine	10	0
10 mgm./kgm. chlorpromazine	10	0

These figures suggest that the effects of chlorpromazine and 2,4-dinitro*ortho*cresol are additive.

Antibody Formation by Protein Components of Bee Venom

IT is not yet known for certain whether the physiological responses to bee venom include the formation of antibodies. Earlier investigators have obtained divergent results when investigating immunization against different effects of the venom. This is probably in part due to the fact that a series of pharmacological and enzymatic reactions are caused by quite different constituents of the venom[1]. In recent years, several proteins with various biological properties have been isolated: first, the pharmacologically highly active toxin-fraction (so-called 'fraction I')[2]; then the enzymes phospholipase *A*[3] and hyaluronidase[4], which on electrophoresis migrate in the so-called 'fraction II'. From these findings arises the question whether antigenic properties may be found with these substances.

Solutions of cautiously dried bee venom were injected intravenously into rabbits at intervals of one to two weeks. Before every injection samples of serum were obtained and stored at − 6° to − 8° C. Repeated doses of 0·2 or 1·0 mgm./kgm. caused increasing formation of antiphospholipase and antihyaluronidase in the sera (cf. Fig. 1). On the other hand, the effects of bee venom on the isolated guinea pig auricle or frog heart, the frog sartorius, guinea pig gut or uterus, and also its systemic toxicity in white mice and the (direct) hæmolysis of human erythrocytes by fraction I, were not diminished by the sera of the immunized rabbits to a greater degree than they were by normal rabbit serum.

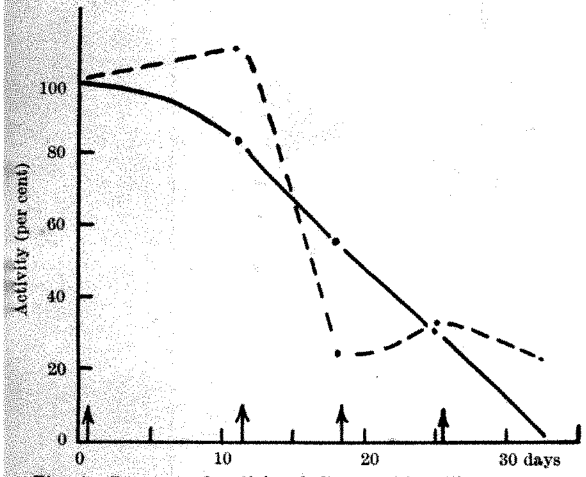

Fig. 1. Increase of antiphospholipase and antihyaluronidase potency of rabbit serum after repeated intravenous injections of bee venom. At arrows: 1 mgm./kgm. bee venom. Activity is given as a percentage of the activity of a control (venom + stored normal serum). ·——·, hyaluronidase (ref. 5); venom, 1 : 20,000, serum, 1 : 40. ·– – –·, phospholipase *A* (ref. 5); venom, 1 : 336,000, serum, 1 : 42

The experiments show that two enzymes—phospholipase *A* and hyaluronidase—of bee venom give rise to immunization, whereas the non-enzymatic but pharmacologically highly active toxin-fraction I seems to be non-antigenic.

The investigations will be extended, and a detailed description of methods and results will be published in the dissertation of one of us (El K.).

Formation of Erythulose from Hydroxypyruvate in the Presence of Yeast Carboxylase

HYDROXYPYRUVATE is a metabolite which can arise from the biological oxidation of glycerate[1], transamination of serine[2], or decarboxylative condensation of glyoxylate[3]. In the presence of cocarboxylase, magnesium ions and transketolase, it yields 'active' (cocarboxylase-bound) glycolaldehyde, capable of forming a ketopentose 5-phosphate with D-glyceraldehyde 3-phosphate[4,5] or sedoheptulose 7-phosphate with D-ribose 5-phosphate[5,6]. Transketolase decarboxylates hydroxypyruvate only when a suitable acceptor aldehyde is present[5] (acetaldehyde will not serve[7]) and does not decarboxylate pyruvate[5,7]. Crude yeast pyruvate carboxylase, on the other hand, has been stated not to decarboxylate hydroxypyruvate[8].

The conclusions of Akabori *et al.*[9] that muscle minces cause a decarboxylative acetoin type of condensation of dihydroxyfumaric acid, leading by way of a hydroxypyruvate intermediate to the formation of tetrose and hexose sugars, led us to re-investigate the action of partially purified yeast carboxylase, prepared from several varieties of yeast, on pure lithium hydroxypyruvate[1]. Contrary to the experience of Meister[8], we observed a slow steady decarboxylation at *p*H 5, and this became vigorous at *p*H 6·5. Colorimetric estimation[1] confirmed the disappearance of hydroxypyruvate, with little or no formation of free glycolaldehyde. A neutral reducing substance accumulated in good yield, having R_F on paper chromatographic analysis in phenol/water of 0·695, identical with that of pure L-erythulose and distinct from that of erythrose ($R_F = 0{\cdot}65$). This enzymically synthesized tetrose gave a crystalline *o*-nitrophenylhydrazone (found N = 16·5 per cent, calc. 16·5 per cent), melting point 150°, unchanged on admixture with authentic erythulose *o*-nitrophenylhydrazone. Determination of the optical rotation in ethanol of this derivative gave $[\alpha]_D = + 48° \pm 3°$, thus characterizing the sugar as L-erythulose. The output of carbon dioxide in relation to the loss of hydroxypyruvate indicates the reaction to be:

$$2\,CH_2OH.CO.COOH \rightarrow CH_2OH.CO.CH(OH).CH_2OH + 2\,CO_2$$

As with pyruvate decarboxylation, the activity is lost on dialysis of the alkaline enzyme-complex, and restored by the addition of cocarboxylase and magnesium ions. Although free glycolaldehyde does not itself yield tetrose, nor does it increase the rate of hydroxypyruvate decarboxylation, free glyceraldehyde can act as an 'acceptor', yielding a ketopentose with these preparations. The possible synthesis of hexose from tetroses and hydroxypyruvate is now being studied, as is also the interesting question of the relationship of these two cocarboxylase-requiring enzymes—carboxylase and transketolase—in the biosynthesis of free sugars from hydroxypyruvate.

Effect of Size and Age of Female Rats on their Response to the Methæmoglobinogenic Action of 3′-Methyl-4-dimethylaminoazobenzene

DURING a study of the methæmoglobinogenic activities of various carcinogenic agents, it was observed that a standard dose of the azo dye, 3′-methyl-4-dimethylaminoazobenzene (16·5 mgm. in ~0·55 ml. of arachis oil per 100 gm. body-weight), induced a greater and more persistent methæmoglobinæmia in old female albino rats than in young female rats.

In the experiment given in detail in Table 1, blood was withdrawn from the tails of four non-fasted rats and checked for the absence of methæmoglobin. Most of our normal rats were methæmoglobin-free but a few showed methæmoglobinæmia of a low order (less than 1 per cent). Two hours later each rat received an injection of the azo dye, and blood (~0·2–0·4 ml.) was taken from the tail at 3, 7, 22 and 28 hr. following the injection. Each fresh heparinized blood sample (0·1 ml.) was mixed with Sörensen buffer (10 ml.; *p*H 6·6) and the percentage of methæmoglobin was determined by a modification of the method of Vandenbelt *et al.*[1]. For convenience of handling, the rats were anæsthetized with ether at each bleeding and in the period 7–22 hr. the animals had access to rat cubes and water.

For statistical calculations, the area which the methæmoglobin-time graph makes with the time axis was found to be a convenient measure of the response of the animal. Alternatively, the sum of th methæmoglobin percentages (Σ per cent) at 3, 7, 22 and 28 hr. could be used. Scatter diagrams o methæmoglobin-time (Fig. 1) or Σ per cent plotted against rat body-weight for 13 young and 11 old animals showed strong linear relationships. Correlation coefficients (r) of $+0·84$ were obtained wit t values of 7·248 and 8·644 respectively, which exceed the 0·1 per cent probability-level. The results ar highly significant.

Table 1

Rat		Per cent methæmoglobin at the stated times (hr.) after injection of the azo dye					Methæmoglobin-time (cm.^{2})
Wt. (gm.)	Age (mon.)	0	3	7	22	28	
245	18	0	16·4	34·5	13·1	6·2	60·7
230	18	0	23·1	32·0	5·7	4·1	57·0
125	2	0	5·9	14·6	2·1	1·5	23·5
125	2	0	4·3	8·2	1·7	1·1	14·1

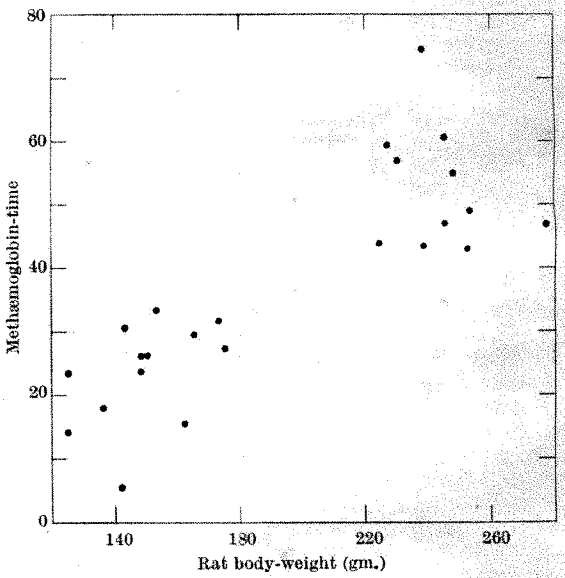

Fig. 1

A complete correlation between methæmoglobin time and age could not be made owing to uncertaint about the ages of most of the old rats. However, th ages of the young animals were known precisely an a linear correlation was found for this group. Her r was $+0·61$ with $t = 2·521$, which exceeds the 5 pe cent level and indicates that the result is probabl significant. The susceptibility of female rats to th methæmoglobinogenic action of the azo compoun appears to increase rapidly during the first fe months of life.

Further information about the groups is given i Table 2. From the methæmoglobin-time varianc figures quoted there, the best estimates[2] of populatio variation were found to be 95·459 and 65·961 fo the old and young groups respectively. The varianc

Table 2

Rat		Age		Body wt. (gm.)		Methæmoglobin-time (cm.^{2})		
Group	No.	Range	Mean	Range	Mean	Range	Mean	Variance
Old	11	8–18 mon.	—	227–277	245·3	42·9–74·6	52·7	86·781
Young	13	56–72 days	64·7 days	125–175	149·6	5·4–33·4	23·5	60·887

ratio, F, is therefore 1·447 (95·459/65·961), which is lower than the 5 per cent level for 10 and 12 degrees of freedom, so that the difference between the standard deviations of the groups is not significant. Thus "Student's" t may be used for investigating the difference between the sample means. The best estimate for the standard error of the difference of the means was 3·650. Since the difference of the means is 29·255, "Student's" t is 8·015 (29·255/3·650), which greatly exceeds the 0·1 per cent level. Therefore, the difference between the mean values of methæmoglobin-time for old and young groups is highly significant.

It is already known that old rats may exhibit markedly different responses to certain drugs as compared with young animals[3]. It would be of interest to determine whether there is a difference in response of young and old rats to the carcinogenic action of 3′-methyl-4-dimethylaminoazobenzene. Some observations of Druckrey and Küpfmüller[4] suggest that old rats require less 4-dimethylaminoazobenzene than do young rats for liver tumour formation.

Since very little work appears to have been done on the methæmoglobinogenic action of azo compounds, it may be noted here that, mole for mole, 4-dimethylaminoazobenzene has been found to be a more potent methæmoglobinogenic agent for rats than its 3′-methyl derivative. The non-carcinogens, azobenzene, 4′-methyl-4-dimethylaminoazobenzene and 4′-hydroxy-4-dimethylaminoazobenzene, had no methæmoglobinogenic activity, but rats which received the last-mentioned compound succumbed to pulmonary œdema. The non-carcinogen, 4-diethylaminoazobenzene, which also produced pulmonary œdema in rats, gave rise to a transient methæmoglobinæmia.

It has also been found that the methæmoglobinogenic activity of 3′-methyl-4-dimethylaminoazobenzene is suppressed when the carcinogenic hydrocarbon, 20-methylcholanthrene, is incorporated in the azo dye–arachis oil solutions. In these circumstances, the methæmoglobin level in the blood invariably drops during the 3–7 hr. period after injection. Further studies of this effect are in progress because it may be related to other effects which have been observed when methylcholanthrene is given to rats receiving the azo dye, namely, inhibition of liver tumour formation[5], diminution in azo dye binding by liver proteins[6] and increase in amounts of liver enzymes which are able to affect demethylation and azo linkage reduction of 3′-methyl-4-dimethylaminoazobenzene[7].

This work was supported by the Melville Trust, to which my thanks are due. It is hoped to publish a more detailed account later.

Biological Activity of Benzoxazine-1,3 Derivatives, particularly against Experimental Sarcoma

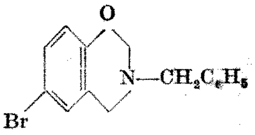
IT has already been shown by Šlopek and one of us (T. U.) that 1,3-oxazine derivatives have a marked antituberculous activity *in vivo*. However, those compounds which are derivatives of nitroparaffins and contain a nitro-group show a relatively high toxicity on prolonged administration. This led one of us (T. U.) to look for less toxic derivatives of 1,3-oxazine[2].

Continuing further this line of research, a number of derivatives of benzoxazine-1,3 have been prepared according to Burke[3] and examined from the point of view of their antituberculous activity.

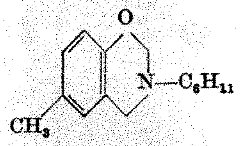
All of them show a tuberculostatic action *in vitro* at concentrations 8–31 mgm. per cent[4].

It has now been found that benzoxazine-1,3 derivatives reduce tumours produced by experimental Crocker sarcoma in mice.

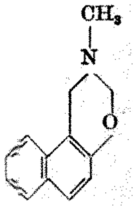
The experiments were carried out by determining the lethal doses when administered subcutaneously. The substances were as follows:



*T*339



*T*375



*T*356

Their lethal and therapeutic doses are given in Table 1.

Table 1

	Concentration (per cent)	Lethal dose for mice of 18–22 gm.	Therapeutic dose for mice of 18–22 gm.
T 339	1·5	30 mgm.	5·0 mgm.
T 375	2·0	5 mgm.	0·2 mgm.
T 356	1·5	10 mgm.	1·2 mgm.

All mice were grafted with Crocker sarcoma. Administration of the drugs subcutaneously was started the day after inoculation. Ten injections of *T* 339 and *T* 375 and eleven of *T* 356 were given during fourteen days. After that, the animals were killed and tumours were examined histologically. The weight of tumours was determined and served to estimate the activity of the drugs.

The results are shown in Table 2.

Table 2

Substance	Total amount of drug (mgm.)	No. of mice				Average weight (mgm.)		Ratio of tumour weights $\frac{c}{e}$
		Experimental		Controls		Experimental *e*	Control *c*	
		♂	♀	♂	♀			
T 339	50	10	—	10	—	855	1,377	1·6
T 339	50	—	10	—	9	1,500	3,093	2·0
T 375	2	8	12	9	10	576	1,441	2·50
T 356	13·2	9	10	9	11	298	944	3·17

It is evident that the substances *T* 375 and particularly *T* 356 inhibit growth of experimental sarcoma tumour. The relatively high toxicity of the substance should, however, be emphasized.

Detailed description of the experiments, including histological examination, will be reported elsewhere.

Œdema Formation in Rat's Skin

It is known that histamine liberators such as 48/80, egg white and dextran produce in rat skin œdema and capillary changes which lead to accumulation of circulating colloidal dye. These changes show a characteristic distribution and occur in skin regions, such as those of feet and face, which are particularly rich in histamine[1]. However, the part of histamine in these changes has been questioned. When discussing these changes it is necessary to deal separately with the œdema formation and the dye accumulation. The œdema is a sign of greatly increased capillary permeability. Concerning the accumulation of a circulating colloidal dye such as trypan blue, the present concept is that the dye is bound in the bloodstream to plasma proteins which penetrate the dilated capillary wall, moving through the dilated capillaries into the damaged area. The mechanism for this penetration is the phagocytic activity of the endothelial cells, histiocytes and fibriocytes which take up the proteins. The accumulation of circulating dye thus indicates an increased local phagocytic activity. The present experiments show that release of histamine is responsible for the œdema formation but that the accumulation of circulating dye is independent of histamine release.

According to Feldberg and Talesnik[1] the œdema in the feet of the rat produced by intraperitoneal injection of 48/80 or egg white is due to release of histamine, because it no longer occurred when the skin had been depleted of its histamine by repeated intraperitoneal injections of 48/80. In contrast, Kramer[2] found that the histamine content of the rat's skin did not influence the œdema produced by egg white and that the œdema occurred also when the skin had been depleted of its histamine.

Using the technique of Brocklehurst *et al.*[3], rats were treated with intraperitoneal injections of 48/80 for eight days. After treatment for five days 48/80 no longer produced œdema, and after treatment for eight days egg white (2 ml. intraperitoneally) also failed to cause œdema. These results agree with those of Feldberg and Talesnik and differ from those of Kramer. They show that the œdema formation is dependent on the histamine release.

In rats in which the skin histamine had been depleted by repeated intraperitoneal injections of 48/80 and in which injections of histamine liberators no longer caused œdema, intradermal injections not only of histamine and of 5-hydroxytryptamine, but also of 48/80 and of egg white, retained the property of causing accumulation of circulating dye at the site of the injection. Intradermal injections of saline solution were ineffective. The dye used was trypan blue, which was injected into the tail vein immediately after the intradermal injections. The rats were killed 60 min. later and the inside of the abdominal skin examined for local dye accumulation. Similar results were obtained in two other series of experiments in which either the histamine in the rat's skin was depleted by dextran or egg white instead of by 48/80, or in which the trypan blue was replaced by indian ink. These results show that the changes responsible for the accumulation of dye or indian ink are independent of histamine release and therefore not an effect of histamine. A similar conclusion was reached by Brocklehurst *et al.*[3] for the dye accumulation of passive cutaneous anaphylaxis in rats in which the skin had been depleted of its histamine by 48/80.

Indian ink and trypan blue accumulation was not caused by the liberation of histamine or 5-hydroxytryptamine since these latter two substances were no longer present after the first day during repeated treatments with 48/80, dextran or egg white. Even in the absence of histamine or 5-hydroxytryptamine the reaction of accumulation continues, showing an unchanged functioning of the inflammatory defence mechanism.

Effect of Blood on the Viability of Dried Cultures of Cholera Vibrios

Between 1949 and 1954 twenty-two strains o *Vibrio cholerae*, grown at 37° C. on 'Lemco' agar and suspended in 'Mist. desiccans'[1], were dried by the spin-freeze method developed by Greaves[2]. Viable counts were made by the Miles and Misra[3] technique on the suspensions used for drying, and on ampoules of dried material reconstituted at intervals afte drying. In routine tests reconstitution was in 'Lemco broth, which was also used as diluting fluid. Al counts dropped rapidly, thus confirming the experience of others[4,5] that the vibrios were unduly susceptible to drying by sublimation.

Experiment showed that higher viable counts could be obtained (*a*) by using 5 per cent blood broth a diluent, or (*b*) by plating 'Lemco' broth dilutions or blood agar. This suggested that blood provided some essential factor for the recovery of cholera vibrios

Table 1. Viability of *V. cholerae* (N.C.T.C. 8021) on 'Lemco', Serum and Blood Agar

	No. of colonies growing at dilutions					
	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}
'Lemco' agar	cc.	11	0	0	0	0
Serum agar	cc.	unc.	29	4	1	0
Blood agar	cc.	cc.	unc.	27	6	0

cc. = confluent colonies. unc. = uncountable

from the dried state, a factor which was not adequately supplied by serum.

It is possible that the population of *V. cholerae* culture is not homogeneous, and that there are cells able to grow on agar and others unable to do so without the addition of blood. To test this point, subcultures were made from the highest dilutions surviving on blood and on 'Lemco' agar and these were redried by the same method. So far there is no evidence to support the theory of a heterogeneous population, but long-term experiments are continuing.

Coenurus of *Taenia brauni* Setti parasitic in Man and Animals from the Belgian Congo and Ruanda-Urundi

In 1952 I was able to observe for the first time the ife-cycle of *Taenia brauni* Setti (1897).

This tapeworm lives, in the adult stage, in the ntestines of dogs and jackals in the Belgian Congo, and its larvæ, of the *Coenurus* type, have been found n Nature in wild rodents (*Lemniscomys striatus* L.).

On feeding laboratory-bred white mice with proglottids found in the droppings of parasitized dogs, I have succeeded in observing the development within them of *Coenurus*. On the other hand, I was successful in obtaining adult worms by feeding non-infected young dogs with fragments of *Coenurus* collected from wild rodents which were naturally nfected with the parasite[1].

Afterwards I discovered the *Coenurus* of this tapeworm in numerous other wild rodents in Ruanda-Urundi (*Rattus r. rattus* L., *Tachyoryctes ruandae* Lönnb. and Gyld., *Otomys irroratus vulcanius* Lõnnb. et Gyld., *Grammomys surdaster* Thom. et Wrought., and *Dendromus pumilio lineatus* Hell.) as well as in a monkey (*Cercopithecus mitis doggetti* Poc.) and in man (native). I never found it in sheep or goats nor n the wild rabbit, although this animal is very common in the region.

In wild rodents the *Coenurus* is most often found under the skin; but it may be found also on other parts of the body, namely, in the pleural and abdominal cavities and in the brain. The percentage of nfected rats varies very much according to the places investigated, but in certain places it may reach up to 20 per cent of the animals examined.

Cerebral coenurosis of rodents has been found only on three *Rattus r. rattus* in the vicinity of Astrida. These *Coenuri* were rather big and situated in different parts of the brain. Two of the three infected rats had also *Coenuri* on other parts of the body.

The case of cerebral coenurosis of the ape was discovered in the region of the Akanyaru (near Astrida). A globular *Coenurus*, 2 cm. in diameter, was found embedded in the parietal lobe. This ape carried two other *Coenuri*: one, of the size of a large pea, was in part nestled in the apex of the heart; the other, much larger, was found in the region of the parotid gland.

In man (native) I have observed eight cases of coenurosis between the years 1948 and 1956, all situated under the skin. Of these eight cases, seven were children, the ages varying between 11 months and 5 years; the last one was a boy of fourteen.

In four children the tumour was found along the ribs, in the four others it was found elsewhere on the trunk. The *Coenurus* was a solitary one in all patients. The dimension of the tumour varied from the size of an almond to that of a large plum; the form being globular or elongated.

The morphological study of all *Coenuri* showed that they belonged to *Taenia brauni* Setti. This tapeworm is extremely frequent in dogs and jackals throughout the Ruanda-Urundi area and Ituri region (Eastern Congo) and it is, together with *Taenia hydatigena* Pallas, the only cestode of the *Taenia* genus found in the dog of these regions[2].

It is my opinion that the *Coenurus* found by Taramelli and Dubois under the skin of a native woman (of the Belgian Congo) belongs also to *Taenia brauni*[3].

It is known that *Coenuri* of *Taenia serialis* or of *Taenia multiceps*, as parasites of man, occupy on this accidental host the same site as on the habitual intermediary host: respectively under the skin for *Coenurus serialis* and in the brain for *Coenurus cerebralis*.

The larva of *Taenia brauni* is less specific in the choice of its location in its natural hosts than those of the preceding species. It seems to me most probable that it would behave in the same manner in man, and that, besides its normal location under the skin, one may expect to find it in the inner organs as well as in the brain. In this connexion it may be pointed out that, during recent years, four cases of human cerebral coenurosis have been described in South Africa all attributed by the authors to *Taenia multiceps*[4]. It could be that these *Coenuri* belong, in fact, to *Taenia brauni*.

Histological and Histochemical Observations on the Intestinal Cells of Lambs and Kids absorbing Colostrum

It has been known for many years that intact colostral globulins are absorbed from the intestine of the young ruminant[1] and recently it has been shown[2], in the calf, that labelled globulins from colostral whey passed from the intestinal lumen into the intestinal lymphatics. Histological examination of the intestinal epithelium of calves in which absorption of protein was taking place revealed the presence of numerous globules with similar staining properties to the protein of the whey, and hence it was suggested that the protein, which was absorbed without change, passed through the cells of the epithelium of the small intestine[3].

We have recently carried out a histological and histochemical study of the intestinal epithelium of young lambs and kids which were killed shortly after receiving colostrum. As in the calf, the epithelial cells of the villi of animals up to 36 hr. old contained large numbers of eosinophilic globules of varying size (2·5–15μ), while the cells of older animals did not contain globules. The globules were present throughout each cell, the majority occupying an infranuclear position since most of the nuclei were close to the free border of the cell.

As described by Comline *et al.*, colostral whey with similar staining and histochemical properties to the globules was present in the lumen of the gut and between the intestinal villi. In this position the whey was in a finely granular form. Moreover, finely granular material with similar staining and histochemical properties was demonstrable in the lacteals within the villi. Examination of suitably stained sections (periodic acid – Schiff) revealed numerous small granules just within the free border of each epithelial cell. These granules had similar staining properties to the globules and hence it appeared that the material in the lumen of the intestine was absorbed in a finely divided form and that globule formation occurred within the cell. Although in mounted paraffin sections the globules appeared homogeneous, examination in water of sections stained with methylene blue revealed that each large globule was made up of a number of smaller globules. Breakdown of the globules apparently occurred within the cell since none could be demonstrated in the lacteals.

Table 1

Histochemical test	Lumen content	Globule	Lacteal content
Periodic acid – Schiff (PAS)	+	+	+
PAS after diastase	+	+	+
PAS after hyaluronidase	+	+	+
Metachromasia	−	−	−
Methylene blue extinction	Faint or nil below *p*H 4·0	Faint or nil below *p*H 4·0	Faint or nil below *p*H 4·0
Alcian blue	−	−	−
Sudan III and IV	+	−	+
Sudan black *B*	+	−	+
Nile blue sulphate	+	−	+
Millon reaction	+	+	Faint +
Feulgen reaction	−	−	−
Pyronin	+	+	+
Pyronin after ribonuclease	+	+	+

The results of the histochemical tests are presented in Table 1. They showed that the material in the lumen of the gut, the globules in the epithelial cells and the material in the lacteals was muco- or glycoprotein. It seems reasonably certain, therefore, that the globules were, in fact, the colostral proteins. That the protein was present as a conjugated protein was not unexpected since highly purified preparations of colostral globulin have been shown to contain residual carbohydrate material[4,5], and fractions of serum globulin have also been shown to fall into the group of glycoproteins[6]. It is possible, however, that the colostral globulin became associated with the mucus secreted by the digestive tract prior to absorption. This point is being investigated.

Terminology of the Insect Integument

A WORKER proposing to investigate the covering ayers of the Insecta quickly finds that he has to contend with a confused and often contradictory terminology. This state of affairs derives from three principal ources ; a detailed knowledge of the coverings has ecome possible only through technical advances nade over the past thirty or so years ; students have requently accepted, rather uncritically, the older erminology ; and, as yet, relatively little is known of he coverings throughout the class, and the necessary omologies on which a standard terminology must be ounded are therefore wanting.

While these are undeniable facts, it is equally ndeniable that unless some action is taken, confusion vill be augmented as time goes on. Moreover, there re sufficient, even though elementary, data on which o base a consistent terminology, simple yet capable of xpansion to meet future needs. To be acceptable uch a terminology demands that the introduction f new terms be minimized, and that those which are vell established be clearly defined, or, if necessary, e-defined to avoid ambiguity.

The term 'integument' as denoting the unicellular ayer with its internal limiting membrane and its uter secreted covering is now in general use. 'Basement membrane' is also the standard term for the nternal bounding membrane of the cellular layer. or the latter, 'epidermis' and 'hypodermis' are about qually popular. Indicating as it does the location of he cellular layer with reference to the secreted part f the integument, and being used in a less general ense than is 'epidermis', 'hypodermis' could well be ccepted and 'epidermis' dispensed with.

To all entomologists the external secreted part of he integument is known as the 'cuticle'. The value f this term has to some extent been lessened by the hoice of 'epicuticle' for the thin outer non-chitinous art of the cuticle. However regrettable this may be, t is now too late to effect any change. For the larger nner chitinous part of the cuticle, the 'procuticle' of Richards[1] appears to be the only term yet proposed, though it has not attained the currency it merits.

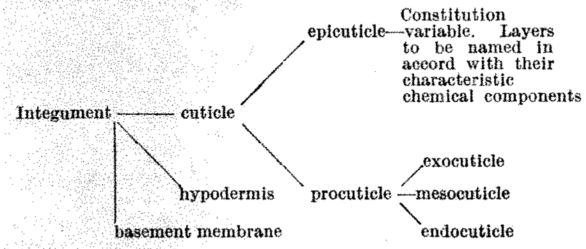
Both procuticle and epicuticle consist of zones variable in number, size, and composition. The only consistent terminology for the procuticle is that of Richards[1] including the modification of Schatz[2] which Richards[3] accepts. He regards the procuticle as consisting of from one to three zones. He restricts the term 'exocuticle' to the hardened part of the cuticle, commonly amber, brownish or black in colour, which is both impregnated and sclerotized. The 'mesocuticle' is that part which is impregnated but not sclerotized, and which is stained by acid dyes, for example, the acid fuchsin of Mallory's stain. The 'endocuticle' is that part of the cuticle which remains chemically unchanged after it has been deposited. This terminology is used in the United States, on the Continent, and in Australia, and it is to be hoped that its adoption eventually becomes general.

It is the terminology of the least-known part of the cuticle, the epicuticle, that is most unsatisfactory. Wigglesworth distinguished four layers in the epicuticles of *Rhodnius*[4], *Tenebrio*[5], and *Periplaneta*[6]. Beginning with the outermost, he named these the 'cement', 'wax', 'polyphenol', and 'cuticulin' layers respectively. Following his example, his followers have exercised considerable ingenuity in interpreting the epicuticles of the insects they have studied in terms of this system. Wigglesworth's terminology was not accepted by Richards[1] nor Dennell and Malek[7,8]. As a result of their work, Dennell and Malek accepted the presence of the cement, wax and cuticulin layers but considered the evidence for the presence of a distinct polyphenol layer insufficient. In place of it they claim that there is a thin 'paraffin' layer. While this is the most recent authoritative pronouncement on the subject, it must still be accepted with reserve. Even among the relatively few species which have been adequately studied, there is a considerable proportion of the epicuticular layers which cannot be homologized in accord with any one proposed scheme. Richards outlined a terminology similar in some respects to that of Dennell and Malek. He proposed the substitution of the term 'tectocuticle'[1] for the earlier 'cement layer' on the grounds that the use of 'cement' in this manner was contrary to histological practice. His term is unfortunate since it suggests the presence (not intended by Richards) of a third major division in the cuticle. Further, he does not propose to use it in the strict sense that 'cement layer' is used, for he himself points out (p. 170) that his term can apply equally to the thin outer protecting layer overlying a wax layer as in *Rhodnius* and *Tenebrio* (that is, as a synonym for 'cement layer'), to the wax layer of the Aleurodidae, to the secretion of the 'peristigmatic' glands of insects, and to the grease layer of ixodid ticks. Obviously, such a term is too general to have any value. Whatever its demerits, the term 'cement layer' is innocuous and non-committal, and as used by Wigglesworth and Dennell and Malek refers only to the thin external layer which overlies the wax layer in a four-layered epicuticle.

In the present state of our lack of knowledge, nothing can be a greater hindrance to progress than an attempt to erect a rigid terminology for the epicuticle. The wisest course to follow is to begin the study of each species with a minimum of pre-conceived ideas as to the constitution of its epicuticle, to determine the number and composition of its layers as found, and to name these according to their characteristic chemical components. This was Dennell's method in dealing with *Sarcophaga*[9] and no better has yet been suggested. Such a method will eventually accumulate data sufficiently comprehensive for precise generalizations to be made.

Finally, a term is needed for the 'skin' shed by an immature insect when it moults. 'Exuviae' is a Latin plural having no singular form. The word itself is ugly, and the various singular forms coined from it are even more so, as well as being etymologically indefensible. None of these is accepted by anyone except its user. Until a generally acceptable term is proposed my own practice is to use the words 'slough' and 'sloughs' with their ordinary English signification.

Based on what has been said above, the following system of terminology is presented for consideration :



Integument
cuticle
epicuticle
Constitution variable. Layers to be named in accord with their characteristic chemical components
hypodermis
basement membrane
procuticle
exocuticle
mesocuticle
endocuticle

Gibberellic Acid and the Growth of Crop Plants

GIBBERELLIC acid has been found to increase the height of a wide variety of plant species in small-scale experiments[1,2]. We summarize here the results of larger-scale experiments on crops growing in the field which began in July 1953 and continued for the next three years.

Preliminary work showed that 2 oz./acre o gibberellic acid in 100 gallons of water was th optimum rate of application, and this was afterward used in most of the randomized and replicated plo experiments. Lower spray-rates and dust application were less effective. Four to ten weeks after treatmen each plot was cut, the grass weighed and sample for dry weight and crude protein (total nitrogen determinations.

The experiments were carried out on varied sward at four different centres. Nevertheless they all gav basically similar results. Gibberellic acid increase the growth-rate of all components of the swards Dicotyledons had longer internodes and petioles while grasses produced longer, though narrower leaves. These effects were observed even unde conditions when there was little or no response t fertilizer alone. Typical dry-weight yield increase are shown in Table 1. The considerable variation were not unexpected, because of differences in th nature of the experimental sites, the grass species the prevailing weather conditions and the length o time between treatment and cutting. The nitroge content of the grass was lowered by about 2 per cen after treatment with gibberellic acid, so that th yields/acre of crude protein were not increased t the same degree as the dry-weight yields.

The initial growth response to gibberellic acid wa more rapid than that to nitrogenous fertilizers. Th difference persisted longer in the spring and autumn when the natural growth was slow, than at othe times of the year. Eventually, however, the yield obtained with fertilizers became greater than thos obtained with gibberellic acid. For example, in th spring, 2 oz./acre of gibberellic acid and 2 cwt./acr of fertilizer gave approximately the same increase yields if the grass was cut within five weeks of treatment ; but if the cut was delayed longer, the increases obtained with fertilizer were up to thre times those obtained with gibberellic acid.

The increase of growth obtained after treatmen with gibberellic acid was accompanied by a temporar chlorosis of the grass. The normal green colou returned within six to eight weeks, or, if a nitrogenous fertilizer was applied together with th gibberellic acid, within a much shorter time. Th yield increases given by gibberellic acid and fertilizer applied together, were additive.

If, after cutting, the grass was allowed to gro again without further treatment with gibberellic acid the dry matter and crude protein yields at a secon cut were depressed by approximately the amount o the increase at cut 1 (Table 1). Consequently, th total yield over the two cuts was not significantl

Table 1. DIFFERENCES IN THE DRY-WEIGHT YIELDS OF GRASSLAND AT TWO CUTS FOLLOWING TREATMENT WITH GIBBERELLIC ACID

Date of treatment	Dry weight yields at cut 1			Dry weight yields at cut 2

All differences, except those marked with an asterisk, were significant at the 1 per cent level.

increased. There were no significant differences at subsequent cuts.

The causes of the reduced growth-rate after the first cut are not fully understood. Depletion of soil nutrients by initial rapid growth is unlikely to be a factor, since application of fertilizer between the cuts had no effect. There was, however, more bare ground on the plots treated with gibberellic acid than on the controls after the first cut, which would indicate that a greater proportion of top growth, particularly of clovers, was removed. This may have checked the re-growth[3]. On the other hand, large decreases of yield at cut 2 were occasionally obtained when the increase at cut 1 was small. This suggests that gibberellic acid had some direct influence on re-growth. It did not, however, cause any permanent change in the composition of the sward.

Experiments on arable crops showed that greater growth of aerial parts of the treated plants was not accompanied by increases in crop yields. For example, wheat treated in the early spring showed a rapid initial increase in growth-rate, but the grain and straw yields at harvest were not greater than those of untreated plants. Similarly, the crop size of tomatoes, peas, runner beans and blackcurrants was not increased when the plants were sprayed with gibberellic acid during flowering or early fruit-set, in spite of a marked increase in the vegetative growth. In other experiments the yield of root crops, including potatoes, turnips and carrots, was even decreased in spite of stimulation of the growth of the tops.

If gibberellic acid could be used in practice for the production of early- and late-season grass, it would be of interest to the dairy farmer only where conditions allow the herbage to be used efficiently. It is difficult to assess the economic return from extending the growing season in this way, particularly since the total yields from swards treated with gibberellic acid are not increased. The use of gibberellic acid in grassland practice seems unlikely.

A fuller account of this work is being prepared for publication elsewhere.

Action of Day-length upon the Formation of Adventitious Buds in *Bryophyllum tubiflorum* Harv.

In recent experiments I have found that day-length strongly influences the formation of adventitious buds in *Bryophyllum tubiflorum* Harv.

Two series of young plants were selected: one was grown during short days (8 hr.), the other during long days (16 hr.), in an ordinary greenhouse in summer. The plants of the two series grew normally; however, progressively, the 8-hr. plants began to differ from the 16-hr. plants in two principal respects: (1) their stems and leaves remained somewhat smaller; (2) already in the first months of culture, the former were totally unable to produce new adventitious buds, whereas in the same time, the long-day plants produced a great number of such buds.

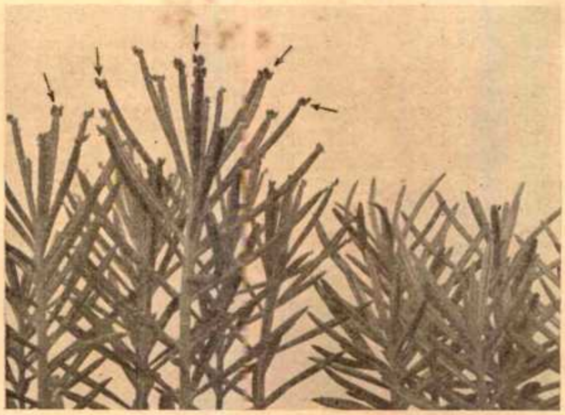

Fig. 1. Adventitious buds on *Bryophyllum tubiflorum* Harv. leaves after 4-month culture. Left, 16-hr. plants; right, 8-hr. plants. Only the long-day plants produce buds (arrows)

The situation became still more marked during the following months until the end of the experiment (4 months): only the leaves of the 16-hr. plants had initiated adventitious buds (Fig. 1).

It could be demonstrated that this effect is related to differences in the internal properties of the leaves of the two kinds of plants, caused by the day-length they had received. This is particularly evident in the following experiment.

After 4 months culture, all the leaves were removed from the 8-hr and 16-hr. plants and placed horizontally on a moistened sand surface. The culture was placed in an ordinary greenhouse in summer with sufficient humidity. One series of leaves were subjected to long-day treatment, and the other to short-day treatment. Thus four series were formed: (1) leaves taken from long-day plants and given long-day treatment; (2) leaves taken from long-day plants and given short-day treatment; (3) leaves taken from short-day plants and given long-day treatment; (4) leaves taken from short-day plants and given short-day treatment.

Only the long-day leaves (series 1 and 2) were able to produce new adventitious buds; these buds were normally situated at the apical end. At the same time, the short-day leaves (series 3 and 4) remained incapable of initiating such buds. However, after one month of culture on moistened sand, these short-day leaves began to develop a certain number of young buds at their basal end, where the long-day leaves had produced very few after several months.

It should be noted that the result was the same when the separated leaves were given either long-day

Table 1. Effect of Day-length upon Bud Formation by *Bryophyllum* Leaves. Number of Buds made by 50 Cut Leaves per Series, in a Period of Three Months

Series	*Bryophyllum* mother-plants cultivated in:	Cut leaves placed in:	No. of apical buds	No. of basal buds
1	16 hr.	16 hr.	63	6
2	16 ,,	8 ,,	57	5
3	8 ,,	16 ,,	9	18
4	8 ,,	8 ,,	0	11

(series 1 and 3) or short-day (series 2 and 4) treatment. This indicates that after the cutting of the leaves the day-length has no noticeable action upon bud formation; only the day-length given to the mother-plant before cutting has a decisive effect (Table 1).

There is no doubt that day-length influences profoundly the properties of the *Bryophyllum tubiflorum* leaves, modifying specially their polarity in regard to adventitious bud formation.

Biosynthesis of Citric Acid in Citrus Fruits

No detailed study has so far been made to find out the mechanism of the formation and accumulation of citric acid in citrus fruits even though studies on the change of acidity and *p*H during ripening have been reported[1]. Investigations are in progress in this laboratory to study the biosynthesis of citric acid in citrus fruit (*Citrus acida*), as a preliminary to which an attempt has been made to locate the stage during the growth of citrus fruit at which citric acid can be detected. The results of the investigation are recorded here.

Fruits used in this investigation were obtained from a plot of thirty trees from a citrus fruit farm. A large number of fruit buds, all of 0·4 cm. diameter, were selected for the investigation, and at different stages of their growth fruits were removed and analysed for acidity and citric acid content. Chromatographic studies were also carried out to detect the different organic acids present.

The samples of the fruit were collected fresh from the trees, the outer skin removed, and a known weight of the tissue immediately homogenized in a Waring blendor for 3–4 min. with a minimum known amount of water. An aliquot of this homogenate was filtered through a funnel and this filtrate made up to a known volume. The filtrate was then suitably diluted and the free acidity estimated by titrating against standard sodium hydroxide using phenolphthalein as indicator. The citric acid was estimated by the method of Saffran and Denstedt[2]. The results are expressed as percentages of total dry weight of the samples taken. Fig. 1 shows the changes in free acidity and citric acid content at different stages of development of the fruit.

The concentrated samples of the filtrates were chromatographed to detect the presence of different organic acids. Descending one-dimensional paper chromatography with Whatman No. 1 filter paper was used for this purpose. The solvent employed was a mixture[3] of butanol, formic acid and water in the ratio of 5 : 1 : 4. The developed chromatogram was sprayed with bromocresol purple reagent. The chromatogram is shown in Fig. 2.

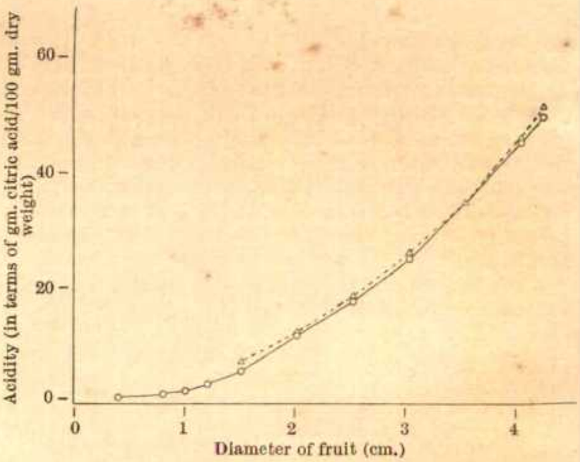

Fig. 1. △ — — △, Citric acid; ○ —— ○, free acidity

It is clear from the chromatogram that in the case of fruits having a diameter of 1·5 cm. and greater, citric acid is the predominant acid with small amounts of malic acid, whereas at younger stages of growth succinic acid is the predominant one with small amounts of two other acids (x_1 and x_2) which are yet to be identified. This shows that the fruit tissues are specialized tissues regarding the formation and accumulation of citric acid and that they are different from those of leaves or stems where citric acid is detected at all stages of their growth (unpublished results). Further, citric acid formation and accumulation in fruits may not be due to translocation from the leaves but to the conversion of sugars into acids by

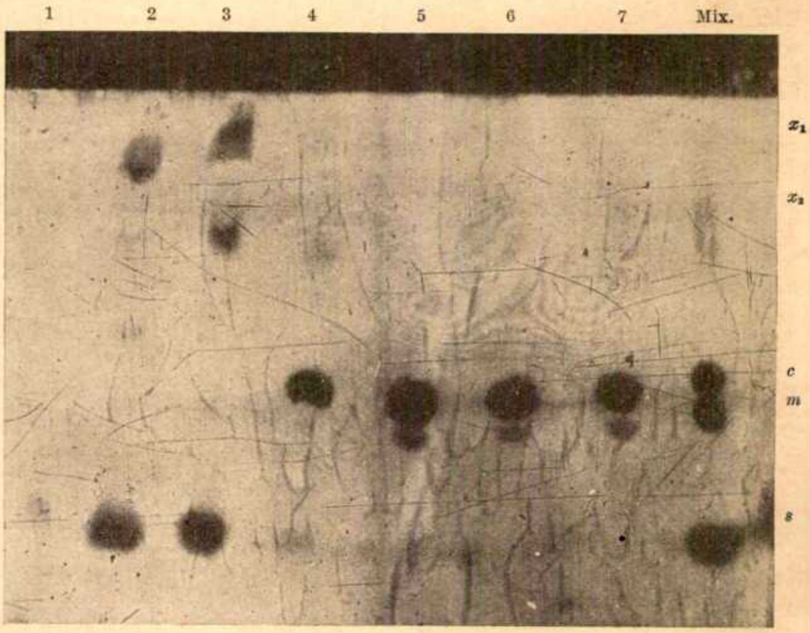

Fig. 2. Chromatogram showing different organic acids present at various stages of development of citrus fruit. Mix. = standard mixture consisting of citric, malic and succinic acids; 1 = 0·4 cm.; 2 = 0·8 cm.; 3 = 1·2 cm.; 4 = 1·5 cm.; 5 = 2·5 cm.; 6 = 3·5 cm.; 7 = 4·4 cm.-diameter fruit extracts

the enzyme system present in the fruit tissues. Details will be published elsewhere.

Our thanks are due to the authorities of the University for financing this project and for the award of a research assistantship to one of us (T. N. S. V.). Our thanks are also due to B. N. Patel and Sons for the generous supply of citrus fruits and to Dr. V. G. Pathak and Mr. Y. K. Sane, of the Botany Department, for taking the photograph of the chromatograms.

Dormancy in Barley

A recent communication[1] suggests that high results in germination tests on barley, carried out in moist sand for 7–10 days, necessarily indicate the absence of 'dormancy' in the sample. It further claims that the 'dormant' condition in barley can be eliminated by desiccation.

The purpose of the present communication is to point out that a live barley corn must be regarded as 'dormant' if conditions can be found under which it fails to germinate but which permit the germination of fully mature grain. A convenient test which meets the latter requirement is as follows[2]: Two filter-paper circles (9·0 cm. diam.; Whatman No. 1 or No. 29) are firmly flattened into the bottom half of a Petri dish (4 in. diam.). The papers are next wetted evenly with water (4 ml.) added from a pipette or burette. One hundred corns of the sample to be examined are then added in such a way that each corn makes full contact with the moist paper. The covered dish is kept in the dark at 18° C. The final count is made after 72 hr.

The result obtained in this test is referred to as the 'germinative energy' of the sample. In the case of a fully mature sample not only is this high but the result is not affected by varying within wide limits the quantity of water available[3]. Less mature barleys frequently respond adversely to increases in the amount of water present during germination and such barleys are termed 'water-sensitive'.

On the above basis, a barley may have low germinative energy[4] even though most of the corns germinate in the prolonged test described by Wellington[1]. Moreover, even if its germinative energy be high, a barley may still prove to be 'water-sensitive' and so appear 'dormant'. For example, in material which had been rigorously dried for seven days at 40°–24° C. and then stored for eighteen days, only 56 per cent of the corns germinated in a water-sensitivity test[3] even though the germinative energy was 95 per cent. Indeed, although it is recognized[5] that desiccation has a marked influence on the 'rate' of disappearance of dormancy in barley during subsequent storage, it is my experience that drying by itself is almost invariably insufficient to convert a dormant barley into a fully mature one.

[4] Pollock, J. R. A., Kirsop, B. H., and Essery, R. E., *J. Inst. Brew.*, 61, 301 (1955); Proc. Eur. Brew. Conv., Baden-Baden, 203 (1955).

[5] Essery, R. E., and Pollock, J. R. A., *J. Inst. Brew.*, 62, 327 (1956).

When applied to germination, 'dormancy' and 'maturity' are not precise terms, and their meaning therefore depends on the particular test which is used. The data in my communication[1] relate to tests in which the conditions were optimal, in all respects, for the germination of barley grains. Complete germination was obtained immediately after the drying treatment, and must necessarily be attributed to the removal of inherent dormancy in the grains which would not otherwise germinate. There is the further significant fact that this response was not only obtained during storage after harvest, but also when the grains were ripening, and at the harvest-ripe stage.

A New Species of *Branchiocerianthus* from a Norwegian Fjord

A specimen of the remarkable hydroid genus *Branchiocerianthus* was caught on July 6, on muddy sand at about 210–240 m. depth in the inner part of the Hardangerfjord on the Norwegian west coast. Previously this genus was known only from the Pacific (Japan, northern Pacific, Gulf of Panama), the Indian Ocean (Somali coast, coasts of Oman and Baluchistan), the Mediterranean (Naples), and the Atlantic (Davis Strait). The new record is thus the first from the eastern Atlantic.

The measurements of the specimen were taken after it had been fixed; but as it did not contract when alcohol was gradually added to the sea water, the measurements are probably valid also for the living animal.

The specimen is apparently fully grown. The hydrocaulus is 110 mm. long and about 2 mm. in diameter, ending below in a small bulb with numerous filaments. The hydranth is diskiform and has the outline of a tennis racket. Its longitudinal diameter is 9 mm., its transverse diameter about 7·5 mm. It is very distinctly bilateral and is attached to the hydrocaulus by its pointed ventral end.

Along the margin of the hydranth are found 54 filiform proximal tentacles. The whorl is interrupted ventrally. The tentacles at the broadest part of the hydranth are about 65 mm. long, the dorsal ones about 30 mm. Towards the ventral margin the tentacles grow gradually shorter, the shortest being almost microscopical.

From the distal third of the hydranth the hypostome emerges. It is about 5 mm. high and ends in numerous filiform distal tentacles 4–5 mm. long, around the transversally placed mouth opening. These tentacles stand in several rows, and are so crowded that it is impossible to count them without destroying the animal; but the number has been estimated at about 50–60.

Between the proximal tentacles and the hypostome, thirty-four blastostyles (four of which are fused) were found, arranged in horseshoe-shape, the row being interrupted ventrally. The smallest blastostyles are situated nearest to the hydrocaulus, the largest ones laterally and dorsally, where they are arranged in two rows. The blastostyles are dichotomously branched and each end branch has the shape of a cluster of grapes.

The colour is pale pink, the blastostyles being pale salmon-red.

Between the blastostyles and the marginal tentacles unbranched radial canals are seen through the transparent wall of the disk. This proves that the specimen is a *Branchiocerianthus* and not a *Branchiaria*. Apart from the radial canals, nothing is known of the internal anatomy; but the external morphological characters alone reveal that the specimen cannot be referred to any of the *Branchiocerianthus* species hitherto described, namely, *B. imperator* (western and northern Pacific, Indian Ocean), *B. urceolus* (Gulf of Panama) and *B. reniformis* (Davis Strait). Nor can it be identical with the underscribed *B. italicus* (Naples), which has a colouring very different from that of our specimen. The Norwegian *Branchiocerianthus* thus undoubtedly belongs to a new species, which has been given the name *B. norvegicus*.

A more detailed description of this interesting form will be given elsewhere.

Potassium–Argon Dating of Plio-Pleistocene Intrusive Rocks

THE potential of the potassium–argon technique in the dating of young rocks can be evaluated by applying it to intrusive igneous rocks which are well dated by conventional geological methods. Because of their possible interest, we are reporting the dating of two such igneous rocks. They occur at Sutter Buttes in the Sacramento Valley, forty miles north of Sacramento, California. Rhyolite plugs of Plio-Pleistocene age intrude and upturn sedimentary formations of late Cretaceous to early Pliocene age. Erosion uncovered the rhyolite plugs before the ensuing period of andesitic intrusions and extrusions, suggesting that the entire igneous cycle covered many thousands of years. Canyons 1,500 ft. deep have since been incised in the sedimentary complex, and much of the volcanic debris which once covered the area to a depth of 500 ft. or more has been stripped by erosion during the time since igneous activity ceased. One of the rhyolite plugs and the youngest andesite block-lava flow were dated. Biotite was used for the age determinations, essentially pure concentrates being obtained by bromoform and diiodomethane methods. Tyler mesh sizes were $-35+150$. A branching ratio of 0·110 and a decay constant of $0{\cdot}558 \times 10^{-9}$ gm. were used. The pertinent age data are given in Table 1.

Table 1

Number	Rock	Mineral	Weight (gm.)	K (%)	^{40}A (10^{-10} moles)	Age (10^{6} yr.)
KA 101	Sutter Buttes andesite flow	Biotite	16 696	4·04	1·78	1·57±0·24
KA 65	Sutter Buttes rhyolite plug	Biotite	18 734	6·61	3·53	1·69±0·10

The radiogenic ages are thus in agreement with a Plio-Pleistocene age for the rocks and actually place them in the correct order. However, it must be pointed out that, within the errors of the experiment, the ages are the same. Because of the small fraction (0·08) of argon-40 which is radiogenic in *KA* 101, a 1 per cent error in the determination of the ^{36}A/^{40}A ratio gives rise to a 12·5 per cent error in the age. This error in the ^{36}A/^{40}A ratio arises from mass discrimination effects in the spectrometer and from limitations on the accuracy of measurement of the argon-36 peak. In future runs, we will attempt to minimize the influence of these factors by running a normal air-argon sample in the spectrometer immediately after the rock-argon, and by more sweeps (twenty-five) on the spectrometer. This work was supported by the Atomic Energy Commission.

Lavoisier's Laboratory Note-books

IN the review of the first part of the *Correspondance* of Lavoisier in *Nature* of November 17, p. 1081, it is said that "M. Fric has also traced the missing volume of Lavoisier's note-books". This is based on a statement in the book reviewed. The second volume of Lavoisier's laboratory note-books is still sometimes said to be missing, although its location was pointed out in 1902 by Brocard in the *Comptes Rendus*[1]. It is *MS.* 61, *ancien* 59, in the library of Perpignan and was presented by Arago, who has written on the cover: "offert respectieusement à la Bibliothèque publique de la ville de Perpignan, par F. Arago". Arago, the distinguished physicist, was born in Perpignan. The document consists of 122 leaves, covering the period September 9, 1773, to March 5, 1774, and a note by Arago says: "Ce cahier renferme les célèbres experiences sur la calcination des métaux en vases clos, et les premières tentatives de Lavoisier sur le combustion du diamant". In the same note, Brocard gives a list of libraries in France containing documents by Lavoisier. Brocard's note seems to have been overlooked, but my attention was directed to it many years ago by the late Dr. Max Speter, who had an unrivalled knowledge of Lavoisier. M. Fric promises to publish the document in full "some day"; a summary only of its contents was given by Berthelot[2].

FORTHCOMING EVENTS

Monday, December 17

Institute of Metal Finishing (at the Northampton Polytechnic, t. John Street, London, E.C.1), at 5.30 p m.—Annual General eeting. 6.15 p.m.—Mr. D. R. Newman and Mr. J. E. Entwhistle Mr. L. Edridge: "Metal Cleaning".

Royal Geographical Society (joint meeting with the Alpine lub, at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. lbert Eggler: "Swiss Ascent of Everest and Lhotse".

Tuesday, December 18

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. Andrew Young, Mr. . A. Longden and Mr. B. L. Metcalf: "Post-War Developments the Coal Mining Industry".

Institution of Electrical Engineers, Measurement and ontrol Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—iscussion on "Breakdown in Dielectrics", opened by Mr. G. G. arton and Mr. J. H. Mason.

Institution of Mechanical Engineers, Industrial Administration and Engineering Production Groups (at 1 Birdcage Walk, estminster, London, S.W.1), at 6.45 p.m.—Discussion on "Case udies from the Application of Planned Maintenance".

Wednesday, December 19

Royal Meteorological Society (at 49 Cromwell Road, London, .W.7), at 5 p.m.—Mr. G. N. Plass: "The Influence of the 9 6 Micron zone Band on the Atmospheric Infra-red Cooling Rate"; and The Influence of the 15 Micron Carbon-dioxide Band on the Atmospheric Infra-red Cooling Rate"; Mr. P. Hughes: "A Determination the Relation between Wind and Sea-surface Drift".

Royal Statistical Society (at the London School of Hygiene d Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), 5 15 p.m.—Prof. M. S. Bartlett: "Measles Periodicity and Comunity Size".

Royal Microscopical Society (at Tavistock House South, avistock Square, London, W.C.1), at 5 30 p.m.—Dr. N. H. Hartsorne: "Some Applications of Polarization Microscopy".

British Psychological Society, Medical Section (at the Royal ciety of Medicine, 1 Wimpole Street, London, W.1), at 8.30 p.m.—r. John H. Hambling: "The Psychology of High Blood Pressure".

Thursday, December 20

Royal Aeronautical Society (at the Institution of Mechanical ngineers, Birdcage Walk, London, S.W.1), at 10 a.m.—All day ction Lecture on "Transonic Wind Tunnel Testing Techniques".

Institution of Mining and Metallurgy (at the Geological ciety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—r. H. C. Curwen: "A Field Method for the Rapid Estimation of e Oxides of Niobium and Tantalum in Black Sand Concentrates"; r. P. I. A. Narayanan and Mr. G. V. Subramanya: "Laboratory udies on the Beneficiation of some Ferruginous Manganese Ores India for the Production of Ferromanganese".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or fore the dates mentioned:

Research Worker (with a medical or biological qualification and me research experience) to assist in the investigation of the minute ucture and development of nervous and other tissue, including nsitometry and electron microscopy—Prof. G. Causey, Department Anatomy, Royal College of Surgeons, Lincoln's Inn Fields, London, .C.2 (December 19).

Assistant Experimental Officer (male, preferably with a degree chemistry, botany or agriculture and experience of the analysis of dioactive materials, or at least G.C.E. (advanced level) with two ientific subjects) in the Radiobiological Laboratory, for duties ich include the analysis of biological samples for radioactive isotope ntent and associated field work—The Secretary, Agricultural search Council Field Station, Compton Newbury, Berkshire ecember 22).

Lecturer (with a degree in mathematics and teaching experience) the Mathematics Department—The Registrar, The Technical llege, Sunderland (December 22).

Senior Lecturer in the Department of Mathematics; Senior cturers (2) in the Department of Physics; Senior Lecturer d a Lecturer in the Department of Metallurgy—The Registrar, llege of Technology, Suffolk Street, Birmingham 1 (December 22).

Technical Assistant (with Inter.B.Sc. or equivalent, and preably previous experience) at the Central Laboratory, Chiswick, r chemical work—The Recruitment and Training Officer (F/EV. 598), ndon Transport, 55 Broadway, London, S.W.1 (December 22).

Assistant Engineer (with a degree in a scientific subject, and enly interested in the application of scientific methods of research the solution of industrial problems) in the Operational Research ction at Headquarters, London, S.E.1—The Director of Establishents, Central Electricity Authority, Winsley Street, London, W.1, oting Ref. A.E.940 (December 27).

Chief Laboratory Technician (male, with wide experience of laboratory work, and able to produce evidence of administrative capabilities and experience), for duties which include the general overall supervision of laboratory technicians, responsibility for laboratory service units and stores, and the care and maintenance of laboratory equipment—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey (December 31)

Lecturer in Engineering (Civil)—The Registrar, The University, Manchester 13 (December 31).

Lecturer in the Department of Physics, Queen's College, Dundee—Joint Clerk to the University Court, The University, St. Andrews (December 31).

Principal (with high academic qualifications and appropriate educational and administrative experience in a University College or Technical College)—The Clerk to the Governing Body, Woolwich Polytechnic, London, S.E.18 (December 31).

Research Assistant in the Department of Chemistry, for work on the fundamental chemistry of grass conservation—The Secretary, The University, Edinburgh (December 31).

Research Microbiologist in the Domestic Food Preservation Section, Long Ashton Research Station—The Registrar and Secretary, The University, Bristol (December 31).

Head (with high academic qualifications and considerable statistical experience) of the Statistics Section of the Rubber Research Institute of Malaya at Kuala Lumpur, for duties which will include the design of field and laboratory experiments and the conduct of research in statistical matters relating to all branches of the Institute's work—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (January 1).

Lecturer in Experimental Physics—The Registrar, The University, Liverpool (January 2).

Lecturer in Education at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 4).

Research Officer or Senior Research Officer (with a university honours degree in science or agricultural science or equivalent qualifications with entomology as a major subject, and preferably with research experience) in the Division of Entomology, Commonwealth Scientific and Industrial Research Organization (Commonwealth of Australia), to take part in investigations into the biological control of skeleton weed, *Chondrilla juncea* L.—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 180/116 (January 4).

Assistant Lecturer or Lecturer (with special interests in general or inorganic chemistry) in Chemistry—The Registrar, The University, Sheffield (January 5).

Superintendent (science graduate) of the Chemistry Laboratories—The Registrar, The University, Sheffield (January 7).

Assistant Lecturer or Lecturer (preferably with special qualifications and interests in mineralogy and petrology) in Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (January 12).

Graduate (with suitable training in physiology, biochemistry, pharmacology or chemistry) in the Department of Pharmacology and Therapeutics, to assist in research on the effect of drugs on gastric function—The Registrar, The University, Sheffield (January 12).

Polymer Corporation Research Student (with a good honours degree in chemistry or general science, including chemistry), to register for a higher degree, working on cationic polymerization under the direction of Dr. P. H. Plesch—The Registrar, University College of North Staffordshire, Keele Staffs (January 12).

Reader in Mathematics at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 14).

Senior Scientific Officer (with an honours degree in physiology or with veterinary qualifications and postgraduate research experience in physiology) in the Physiology Department, for work concerned with the physiology of temperature regulation—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr, Scotland (January 16).

Official Fellow in Philosophy—The Vice-President, Trinity College, Oxford (January 18).

Reader or Senior Lecturer (highly qualified in statistical theory and widely experienced in the application of statistics to practical problems) in Statistics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

Senior Lecturers (2) in Physics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

Senior Lecturer (with a good honours degree in psychology or equivalent) in Psychology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 8).

Lecturer (with a research degree in nutrition, biochemistry or chemistry, followed by specialization in nutrition or biochemistry) in Biochemistry and Nutrition, at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, February 15).

Lecturer (preferably with interests in the experimental aspects of ecology or taxonomy) in Botany in St Salvator's College—The Joint Clerk to the University Court, College Gate, St. Andrews (February 18)

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics, and subjects allied to chemistry or physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Turner and Newall Research Fellow in Engineering, Inorganic Chemistry, Physics or an allied subject—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Assistant Chemist, Experimental Officer grade, for analytical work on crops and soils—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. No. 1052/9.

Assistant Experimental Officer (female, with a degree in biological science or equivalent qualifications, and also good secretarial qualifications) to be Personal Assistant to the Head of the Physiology Department—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting 56/9.

Chemist (aged 20–30, with a second-class honours degree in chemistry or A.R.I.C., and a genuine interest in the technical aspects of colonial development) in the Chemist's Department, Government of Tanganyika, for general and analytical research work in toxicology, food and drugs, and waters, and the supervision and training of African Assistant Chemists and Chemical Assistants—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.97/8/01.

Chemist (with a first- or good second-class honours degree in chemistry) in the Geological Survey Department, Uganda, for the analysis of ores, rocks and minerals, with particular reference to the ores of tungsten, beryl, niobium and tantalum, and analyses of limestones, and to work in close co-operation with the Department's ore-dressing laboratory—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/9/06.

Hospital Biochemist (Senior grade) at Llandough Hospital, Penarth, Glamorgan—The Secretary, United Cardiff Hospitals, Cardiff Royal Infirmary, Newport Road, Cardiff.

Professor of Chemical Engineering—The Head, Department of Chemistry, University of Saskatchewan, Saskatoon. Sask., Canada.

Research Worker (with some postgraduate experience in research), to take part in a programme of research on the behaviour of normal and malignant cells in tissue culture—The Secretary, University College, Gower Street, London, W.C.1.

Scientific Officer (honours graduate, preferably with some previous research experience) in the Bacteriology Department, to take part in research on the intestinal flora of the pig—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/13.

Senior Botanist (male, with at least a second-class honours degree in natural science or biological science, and at least eight years postgraduate experience in the fields of botany and plant pathology) in the Department of Agriculture, Uganda, to take charge of the Botany and Pathology Section, and to be responsible for all research and advisory services under these heads—The Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD. 63/9/06.

Technician in the Geology Department—The Secretary, The University, Exeter.

Zoologist (or otherwise suitably qualified biologist, B.Sc.), to assist in tissue culture work and implantation of tumours in connexion with studies of radiation effects—The Director, M.R.C. Experimental Radiopathology Research Unit, Hammersmith Hospital, Ducane Road, London, W.12.

New Books

Polymer Solutions

By Dr. H. TOMPA, Research Laboratories, Courtaulds, Ltd.

This book deals with the properties of polymer solutions, firstly in so far as they are relevant to the verification of existing theories on the subject and secondly, in so far as they give information on the weight, size and shape of the polymer molecule in solution. Price 55*s*.

Instrument Technology—Volume II: Analysis

By E. B. JONES, B.Sc., A.Inst.P.

This second volume covers the appropriate portion of the Instrument Maintenance syllabus of the City & Guilds College, London.

In addition to acting as a complete reference book on instruments and instrumentation, this 3-volume work will also be found useful for apprentice training. Price 40*s*.

Disposal of Sewage and other Water-borne Wastes

By Dr. KARL IMHOFF, Dr. W. J. MÜLLER, A.M.I.E.(Aust.), and D. K. B. THISTLETHWAYTE, B.Sc., A.R.A.C.I.

This book is based upon a translation of the 16th edition of Imhoff's well-known "Taschenbuch der Stadtentwaesserung". The contents differ from the German work making it more suitable for use in the countries of the British Commonwealth and the U.S.A. It is designed as a reference work for all concerned with sewage disposal, and will help to solve problems of liquid wastes disposal under practical conditions. Special attention is paid to the disposal of sewage in unsewered areas, and to industrial waste disposal. Price 45*s*.

Modern Methods of Microscopy

Edited by A. E. J. VICKERS

A series of papers reprinted from *Research* dealing with most aspects of microscopy, including microscopic interferometry, the reflecting microscope and its applications outside the visible spectrum, new developments in electron microscopy and the flying spot microscope. Price 15*s*.

LECTURES AND COURSES

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

ACTON TECHNICAL COLLEGE

HIGH STREET, ACTON, W.3

Principal: J. Topping, M.Sc., Ph.D., D.I.C., F.Inst.P.

The following Special Courses will be held during the Spring Term, 1957:

1. Recent Advances in Physical Organic Chemistry. A course of Nine Lectures on Wednesdays, at 7.30 p.m., commencing January 16, 1957 Lecturers: Specialists from Universities. Chemistry of Free Radicals. Reactions of Organic Cations. Aliphatic Substitution. Theories of Autoxidation. Reduction and Hydrogen Transfer. Reactivity in Aromatic Systems. Fee for the course: £1.

2. Modern Aspects of Chromatography. A course of Twelve Lectures on Fridays, at 7.30 p.m., commencing January 11, 1957. Lecturers: Specialists from Research Institutions and University Staffs. Modern Theoretical Aspects. Paper Chromatography. Desalting Techniques. Steroid Chromatography. Chromatography in Medicine and in Inorganic Chemistry. Adsorption Column Chromatography. Vapour Phase Chromatography. Fee for the Course: £1.

3. Modern Chemistry and Technology of Waxes. A course of Twelve Lectures on Thursdays, at 7.30 p.m., commencing January 10, 1957. The courses will cover the complete Modern Chemistry and Technology of Waxes and Wax Containing Materials and their Utilization. Fee for the Course: £1.

4. Laboratory Course on Paper Chromatography. Short Four-day Courses for Industrial Chemists and Research Workers are held each term. Next Course commences December 18, 1956. Fee for the Course: £4.

Further particulars and forms of application may be obtained from the Principal.

COLLEGE OF AERONAUTICS

The Board of Entry of the College invites applications from suitable candidates for the two-year course which begins in October, 1957 and ends in June, 1959. The course is intended for selected students of graduate standard. Candidates who do not possess a university degree may offer alternative evidence of educational attainment, for example, a good higher national certificate with a satisfactory record of apprenticeship or equivalent experience in industry. All applications are considered by the Board of Entry which may call candidates for interview. The College, a postgraduate institution, is devoted to the study of aeronautical science and engineering. The curriculum covers the five main subjects of Aerodynamics, Aircraft Design, Aircraft Electrical Engineering, Aircraft Propulsion and Aircraft Economics and Production. Instruction in the first year is designed to provide all students with a broad background of knowledge in all these subjects, with opportunity for limited specialization in two or three of them. In the second year, students specialize more particularly, usually in one subject. Experiments in the air are an important part of the work, both in the first year when all students take part in them and in the second year when they are linked to the specialist work of the departments. Students who satisfactorily complete the course receive the Diploma of the College.

Further particulars and details of the procedure for enrolment may be obtained from: The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks.

CITY OF BIRMINGHAM EDUCATION COMMITTEE

COLLEGE OF TECHNOLOGY

DEPARTMENT OF PHYSICS

POSTGRADUATE COURSES

Evening Courses in the following subjects begin on Wednesday, January 16, 1957.

Vacuum Technique. Course of Lectures and Laboratory work intended for physicists and engineers engaged in using vacuum techniques and others who require theoretical and practical background knowledge of vacuum processes.

Acoustics and Noise Measurement. Course of Lectures and Laboratory work including the theory and use of acoustical measuring instruments Applicants should have a knowledge of physics to about degree or H.N.C. standard.

Fee: £2 2s. for each course.

Further details and application forms may be obtained from the Registrar, College of Technology, Suffolk Street, Birmingham, 1.

E. L. RUSSELL,
Chief Education Officer.

CHELSEA POLYTECHNIC

(Provisionally designated College of Advanced Technology)

DEPARTMENT OF CHEMISTRY

SANDWICH COURSE IN CHEMISTRY

A Sandwich Course in preparation for the examinations leading to Graduateship of the Royal Institute of Chemistry will commence in January, 1957. The course will be of four years' duration, and will involve six-months study at College and six-months industrial experience The normal requirements for admission to the course will be successes at A Level (G C E), or comparable examinations, in Chemistry, together with Physics and/or Mathematics, and three suitable ordinary level subjects.

Inquiries from individual students, industrial firms, research organizations and government departments will be welcomed Particulars from the Clerk to the Governors, Chelsea Polytechnic, Manresa Road, S.W.3.

UNIVERSITY OF BIRMINGHAM

FACULTY OF SCIENCE

M.SC. COURSE IN RADIOACTIVITY

A course of lectures and practical work in general radioactivity leading to the degree of M.Sc. by examination, is available in the Department of Physics. The course is suitable for honours graduates in physics wishing to obtain special experience in radioactive techniques, including radiochemistry. Graduates in subjects other than physics and graduates who have not obtained honours will also be considered for admission to the course.

M.SC. COURSE IN REACTOR PHYSICS AND TECHNOLOGY

A course of lectures and practical work in reactor physics and technology, leading to the degree of M.Sc. by examination, is available in the Faculty of Science The course is suitable for graduates with a good first degree in pure or applied science (normally physics, mechanical engineering or chemical engineering). Some introductory lectures and tutorial assistance will be provided to bring entrants to the necessary standard of knowledge in relevant branches of both physics and engineering.

These courses will last for one academic year; the fee is £81. A limited number of maintenance awards with remission of fees will be available in connection with each course. Applications for admission to the courses starting in October, 1957, and requests for further information, should be made as soon as possible to the Registrar, the University, Edgbaston, Birmingham, 15.

Graduates wishing to be considered for the Advanced Course Studentships of the Department of Scientific and Industrial Research must apply to the Registrar before February 1, 1957.

THE POLYTECHNIC

REGENT STREET, W.1

DEPARTMENT OF MATHEMATICS AND PHYSICS

The following series of lectures will be held on Tuesdays, from 7 to 8.30 p.m., commencing on January 8, 1957.

THE PHYSICS OF SEMICONDUCTORS
commencing January 8, 1957
SEMICONDUCTOR CIRCUIT ELEMENTS
commencing February 26, 1957

Application for prospectuses and enrolment forms should be made to the Director of Education as soon as possible.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

S.W 7

A course of eight lectures on the Measurement of Temperature in Flames will be given by Drs. A. G. Gaydon and F. J. Weinberg on Mondays at 2.30 p.m., commencing January 21, 1957.

Further particulars from the Deputy Registrar, City and Guilds College, Exhibition Road. S W.7

UNIVERSITY COLLEGE, LONDON, Gower Street, W.C.1 Applications for admission to the B.Sc. (Special) Degree Course in Zoology commencing in October, 1957, must reach the Tutor to Science Students not later than Thursday, January 31, 1957. Selected applicants (who will be notified individually) will be required to take a written and practical test in the Department of Zoology on Thursday, March 21, 1957, from 10 a.m. to 5 p.m. The final selection of candidates for admission will, with certain rare exceptions, be made from those successful in this test.

BOROUGH POLYTECHNIC

BOROUGH ROAD, S.E.1

DEPARTMENT OF ELECTRICAL ENGINEERING AND PHYSICS

A course of thirteen weekly lectures on NUCLEAR PARTICLE TECHNIQUES will be given by members of the Staff of Atomic Energy Research Establishment and p cists from London Colleges and Medical Sch The first lecture will be held on Wednesday, J ary 16, 1957.

The lectures include: detection and mea ment of nuclear radiations, radio-isotope ap tions and health physics and instrumentation.

The course fee is £2. Full particulars and plication forms from the Secretary, Borough I technic, Borough Road, S.E.1.

OFFICIAL APPOINTMEN

UNIVERSITY OF MANCHEST

Applications are invited for the post of Lec or Assistant Lecturer in Mathematical Stati The successful candidate will be expected to a in advisory and research work in addition t teaching duties. Salary scales per annum: turer, £650 to £1,350: Assistant Lecturer, £55 £650; initial salary and status according to q fications and experience. Membership of F.S. and children's allowance scheme.

Applications should be sent not later than J ary 1, 1957, to the Registrar, the Univer Manchester, 13, from whom further partic and forms of application may be obtained.

UNITED OXFORD HOSPITAL

THE CHURCHILL HOSPITAL, HEADINGTON, OXFORD

A Physics Graduate is required in the De ment of Radiotherapy, Churchill Hospital, for pointment in the salary scale £710 to £845. post is expected shortly to be given a Se Physicist grading with a salary scale £910 £1,230, and, if satisfactory, promotion would be made to this grade. The duties include p cal investigations concerned with the clinical of rotation therapy, multicurie cobalt units, voltage X-rays and radioactive isotopes, and some teaching of radiographer students. The partment is expanding and there will be the portunity for original work.

Applications, giving full details and name two referees, should reach the Assistant Adm trator within two weeks of this advertisement

---

UNIVERSITY OF SHEFFIELD

A graduate, with suitable training in physiol biochemistry, pharmacology or chemistry, is quired to assist in research in the Departmen Pharmacology and Therapeutics, on the effec drugs on gastric function. Salary in the r of £550 to £750, depending on qualifications experience. The appointment will be for year initially, renewable for a further two y

Applications, with details of age, qualificat and experience, and the names and addresse two referees, should be sent to the Registra January 12, 1957.

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Lect in Experimental Physics in the Department Physics, where there are good facilities for search in (a) nuclear physics and (b) soft X spectroscopy. The duties of the post will c mence as soon as possible before October 1, 1 The initial salary will be within the range to £1,250 per annum, according to qualificat and experience.

Applications, stating age, academic quali tions and experience, together with a list of lications and the names of two referees, sh be received not later than January 2, 1957. the undersigned, from whom further partic of the conditions of appointment may obtained.

STANLEY DUMBELL,
Registra

UNIVERSITY OF OTAGO

DUNEDIN, NEW ZEALAND

The University proposes to appoint a Lect in Biochemistry and Nutrition at the H Science School. Applicants should hold a rese degree in nutrition, biochemistry, or chemis followed by specialization in nutrition or chemistry. Salary range £985 to £1,235 annum.

Further information may be obtained from Secretary, Association of Universities of the Br Commonwealth, 36 Gordon Square Lon W.C.1. Applications close in New Zealand London on February 15, 1957.

Half-tone printing plates

with an ordinary studio camera

It is now possible to make half-tone printing plates with an ordinary sheet-film camera. 'Kodalith' Autoscreen Ortho Film has the half-tone dots incorporated in the emulsion, making process cameras and half-tone screens unnecessary.

Autoscreen Film can be used with pre-sensitized metal plates to make half-tone or combination line/tone plates for reproduction by office printing machines. Type matter and line drawings can be exposed at the same time as photographs or wash drawings.

Please send for details.

1. Make the normal detail exposure.
2. Flash with yellow light for contrast control.
3. Develop, with controlled agitation.

AUTOMATIC TITRATIONS

Are easily carried out by the E.I.L. Automatic Titrimeter, Model 24. This instrument is fully automatic, switching itself off on reaching the pre-set end point.

Either the volumetric or the coulometric method may be used, and separate titration heads for each type are available. Duplicated connexions are provided on the Control unit.

The endpoint setting dial is calibrated in pH (3 to 11) and in millivolts (+ 400 to − 800), and the equipment can be used for any type of chemical reaction producing a determinate change of e.m.f. The accuracy of titration is 0.05 c.c. in 50 c.c., the limit normal for manual titrations.

The instrument can be used on 110 to 120 V. and 200 to 250 V., 40 to 60 c/s a.c. mains.

CALCUTTA

MAN-POWER PROBLEMS IN THE FACTORY INSPECTORATE OF BRITAIN

In a statement in the House of Commons on May 18, Mr. Robert Carr, the Parliamentary Secretary to the Ministry of Labour and National Service, said that the Minister had just received the report of an inquiry by three senior officers into the staffing and organization of the factory inspectorate, and that it was proposed to increase the strength of the engineering and chemical branch of the inspectorate from eighteen to forty-four, thus permitting one engineering inspector and one chemical inspector to be stationed in each division; further, the strength of the general inspectorate was also to be increased so as to enable inspectors to pay more attention to building operations and engineering constructional work. The report, which was prepared by the Under-Secretary in charge of the Safety, Health and Welfare Department of the Ministry, the Director of Organizations and Establishments and the Chief Inspector of Factories, gave a factual survey of the work and staffing organization of the factory inspectorate and made certain recommendations on some problems likely to arise in the light of future developments. Although the full report has not been published, a White Paper which was issued in October* gives a sufficiently full summary of the results of the survey for a reasonably informed judgment as to the adequacy of its recommendations, some of which, as Mr. Carr announced in May, were immediately accepted by the Minister.

The White Paper is in fact of scientific interest for several reasons. It gives, in the first place, a concise but clear summary of the functions and work of the inspectorate, which enables an independent judgment to be formed as to the importance of technical and scientific knowledge on the part of the inspectors. This chapter also includes a comparison of the work before the War and that to-day, and discusses the factors that have changed or increased its work, and future changes that are likely to affect the work of the inspectorate. It would be difficult to improve on this admirable description of the work of the inspectorate; and since it indicates the place of the inspectorate in the industrial life of Britain and its contribution to industrial efficiency as well as to welfare and safety, it deserves to be read by every scientist engaged in industry. Little imagination on the part of the reader is required to appreciate how much depends on the co-operation of the scientist and technologist if the work of even the strongest and most efficient inspectorate is to have full effect.

The primary duty of the factory inspectorate is to promote and enforce the uniform observance of the provisions of the Factories Acts, and regulations made under the Acts, though inspectors have also duties under the Truck and other Acts in relation to factories. Inspection may take the form of special visits to inquire into particular problems, or may be substantial inspections of a routine character to ensure that there is general compliance with the Acts; and it will be recalled that it was the revelation of a widespread failure to comply with the regulations in regard to precautions against fire that shocked Parliament when Mr. Carr made his statement in May. In these routine visits, attention must be paid not merely to general precautions against fire but also to particular safety problems such as the guarding of machines, the proper maintenance of lifting tackle, boilers, air receivers, etc., and the committee of inquiry considered that thoroughness of inspection was far more important than frequency of visits.

Until December 31, 1954, the inspectorate endeavoured to comply with the general standards of inspection recommended by the departmental committee of 1928 and to visit the more important factories and workshops at least once a year and the less important works at least once in every two years, and to give every works in Britain a thorough inspection within an average period of four years. The standard of an annual visit has never been, and is unlikely to be, achieved, and the revised scheme introduced on an experimental basis on January 1, 1955, appears to receive the unreserved support of the committee of inquiry. Under this scheme the general principle of inspection once in every four years is maintained; but the district inspector, under the direction of the superintending inspector, decides which factories shall be accorded priority for a thorough inspection during the year, having regard to such factors as the nature of the processes, the standard of compliance with statutory requirements, the period since the last thorough inspection, the numbers employed, etc. A small factory with serious risks may have higher priority than a much larger factory where conditions are good, and a factory accorded priority one year may or may not receive priority in the next year.

In view of the subsequent discussion of the work of the inspectorate and its possible reorganization, the figures quoted in the report regarding visits from 1928 to 1955 should be noted. Between 1928 and 1933 there was a comparatively large increase in visits to factories with power, following the increase in staff recommended by the departmental committee. Since then, the number of visits has fallen by 7 per cent, while the number of factories has increased by more than 33 per cent; but taking all factories together, between 1928 and 1955 the number of factories has decreased by 11 per cent, while visits have declined by nearly 22 per cent.

Besides this routine inspection, however, inspectors are instructed to investigate serious accidents, or accidents and cases of disease where there is reason to suspect a breach of the law or some unusual circumstance calling for investigation, and here their function is primarily to ascertain the cause of an accident. This involves visiting the site of the accident and examining any plant or machinery involved as well as questioning witnesses and any informed person, and interviewing the occupier of the factory and other persons in authority. Here clearly technical knowledge can again be of decisive importance; but there is no clear distinction between the inspectorial and the advisory functions of the inspectorate, and such advisory work can lead to much saving of time in the long run, for example, if the advice of the inspectorate is sought when new factories or extensions to existing factories are planned.

---

* Staffing and Organisation of the Factory Inspectorate. Pp. 48. (Cmd. 9879.) (London: H.M. Stationery Office, 1956.) 2s. net.

Although the total number of factories has declined from some 260,000 in 1928 to 230,000 in 1955, the number of power factories has increased by some 64,000, and these factories involve substantially more work in inspection; and the more extensive safety requirements of the 1937 Act have added considerably to the work of inspection. Moreover, to play their part in securing improved conditions, inspectors must keep abreast both of advances in knowledge of the effects of certain dust and fumes on the health of those working in their presence and of the efficacy of precautionary measures. The 1948 Act has also added to the work of inspection, and there have been other developments affecting the work of the inspectorate.

On balance, the increase in the number of works doctors increases the work of the medical inspectors, and a principal reason for seeking to increase medical supervision is to encourage an informed and co-operative approach to problems of industrial health. Industries which present special health hazards are being encouraged to extend their medical services, and to press on with investigations into the reduction of the hazards, either by preventive measures or, where possible, the substitution of less dangerous substances. As a result, inspectors on their visits to factories are required to pay increasing attention to ensuring that the health of the workers is adequately protected, and increasing attention to medical supervision may be necessary in the future.

Some developments in industrial processes have increased, and some have reduced, the work of the inspectorate; but there seems to be little doubt that, on the whole, since 1928 industrial developments have increased the volume and complexity of the work of the inspectors. The report notes the growth of consultation with industry and the work in which such consultation has led to a pooling of technical experience and the improvement of conditions on a practical and scientific basis. Most of this work has fallen on the headquarters staff, and particularly on members of the technical branches, who not only serve on the various committees but also carry out the secretarial work. Furthermore, the report refers to some future developments, such as the Ionizing Radiation Regulations at present under consideration and those relating to the use of inflammable substances, which are likely to add to the volume of the work and to its complexity, if not also to the technical knowledge required of the inspectorate. Mr. Carr said in the House of Commons on October 30, for example, that there is at headquarters a physicist engaged full-time on advising the inspectorate and industry on precautions to be taken in regard to radiation hazards, and that fifteen inspectors have already been to courses on radiological protection at Harwell and an engineering inspector was attending a course on the design of nuclear reactors. Inspectors make special visits to factories where there are known to be radiation hazards, and the Atomic Energy Authority informs the inspectorate of all firms to which isotopes are delivered.

To deal with these changes, the inspectorate has increased from a total of 200 in 1928, which included 5 in the medical, 5 in the electrical and 6 in the engineering and chemical branches, to 378 in 1956, of which 18 were in the medical, 14 in the electrical and 18 in the engineering and chemical branches. Moreover, while about 61 per cent of those entering the inspectorate before the War had technical degrees and 68·8 per cent previous industrial experience, only 13·8 per cent of those entering since the War had technical degrees and 48·8 per cent technical experience. As a result, the proportion of technically qualified persons is much higher in the senior grades of the inspectorate than in the junior.

The problems of the Medical Branch are not considered in any detail in the White Paper, and no recommendations are made regarding the organization and size of the medical inspectorate. This is considered as, for practical purposes, a distinct problem; and while much thought is being given to the best way of developing industrial health services, it would be inopportune to make fundamental changes in the organization of the medical inspectorate in advance of decisions on these questions of policy. None the less, the analysis of the problems and conclusions which constitute Part 2 of the White Paper is of general scientific interest, particularly in view of the fundamental approach to the problems which characterizes its analysis and recommendations. It is not disputed that the inspectorate is too small; but it is emphasized that the decision as to the size of the inspectorate must be realistic and determined in relation to the national shortage of scientists and engineers. No government department should compete for such persons beyond the extent that this can be shown to be essential for the prosecution of its work.

It is refreshing to find such emphasis placed on the decisive importance of making proper and economical use of man-power resources in a context in which the impossibility of conceiving a limit beyond which recruitment of an extra inspector could contribute nothing to improve the safety, health and welfare of factory workers; for it can easily lead, as in the debate last May, to proposals which disregard the consequences of failure to use wisely and fully the special skills of scientists and technologists. Moreover, the White Paper keeps constantly in mind that factory inspection is only a means and not an end, though admittedly a most important means, of achieving the objectives of national expenditure in this field—the promotion of health, safety and welfare in factories. Its recommendations come with reater force in that it envisages the possibility that ew developments in industrial processes, an ineasing proportion of modern well-built factories, ie continuing development of the co-operative pirit in industry and the cumulative effect of the ork of the inspectorate over many decades may ermit a substantial reduction in the resources of ian-power and money devoted to factory inspection.

That time has not yet come; but while the White 'aper admits the necessity for some small overall icrease in the size of the general inspectorate, it does ot suggest that exceptional efforts need be made to icrease the recruitment of technically qualified ersons. Persons with and without technical qualications are both required in the general inspectorate, nd there is no objective answer to the question in hat proportions the two elements should figure. he work of the general inspectors is one and inivisible, and although the range of technical roblems is wide, not all the work is technical, and ie non-technical officers have the assistance of olleagues, and particularly of senior colleagues, who ave technical qualifications. Even the technical fficers have often to deal with many matters outside ieir particular specialities.

While it may well be that a general scientific back-round and attitude of mind will enable an inspector o deal better with technical questions, whether or ot they fall within his special subject, and while it iay also be true that failure to recruit a reasonable roportion of technically qualified inspectors may ead to a serious drop in the quality of the inspectorate s a whole, the committee does not think that the oint has been reached which would justify special fforts to increase such recruitment. Every effort iould be made to increase interest among technically ualified persons at the universities and elsewhere, ut the main effort should be to relieve the inspectors f routine or other work which can be handled elsehere and to provide them with more efficient ervices. Greater advantage should be taken of the pportunities to streamline administration resulting om the fact that the inspectorate is now part of a Ministry, with a nation-wide organization of regional nd local officers, and the inspectorate's boundaries iould be re-aligned to run with those of the Iinistry's regions, subject to exceptions where ecessary.

The detailed work required to give effect to these ecommendations has already been initiated, and a etailed study is also being made of the possibility f relieving inspectors of the non-technical work of nforcing the provisions regarding hours of work. hese are sensible proposals which should reduce the isk of wasting the special knowledge or experience f the inspectorate; and the increase in the Enginering and Chemical Branch already announced hould also help. The posting of a specialist engineer nd a specialist chemist in each division is suggested rimarily to reduce delays and relieve the burden on he specialist inspectors at the central office; but it s probable that some saving of the time of general ispectors should also result. More particularly, owever, it should maintain and develop the technical resources of the inspectorate in the way that makes the most economical demand for the services of professionally qualified scientists and engineers. Lastly, a full-scale review of staff training is now in hand with the object of formulating a policy which takes full account of post-war problems.

The immediate reason for undertaking this survey was the difficulty experienced in recruiting to the factory inspectorate as many men and women with technical qualifications as had been customary in the past. The White Paper does not differentiate between men and women, nor examine the question whether in the present situation increased use might be made of women, particularly of those with technical qualifications. Nevertheless, as a survey of the staffing and organization of the inspectorate it is excellent; its analysis is clear and concise, and its recommendations are sound and practicable. But it is as an appendix to the recent report on Scientific and Engineering Man-power in Great Britain that it is of even greater importance and significance, for it demonstrates the approach to the use of such man-power that is imperative in industry and elsewhere as well as in government departments, if Great Britain is to achieve any solution of its man-power problems.

THE CHANGING FACE OF ORGANIC CHEMISTRY

Perspectives in Organic Chemistry

Edited by Sir Alexander Todd. Pp. x+527. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 7.50 dollars. 55s.

THIS year chemists have celebrated the centenary of Sir William Perkin's discovery and the manufacture of the first synthetic dyestuff, mauveine. They were celebrating also the real birth of organic chemistry, since it was the manufacture of this and of other dyestuffs which provided the real stimulus to investigations into the detailed structure and reactions of organic compounds. A perusal of Perkin's original memoirs and other publications of this period shows that in 1856 chemists had no knowledge of the structure of organic compounds and it was not until nine years later, in 1865, following Kekulé's classical paper on benzene, that any real progress was possible.

During the past fifty years it is doubtful if any individual chemist has made a greater contribution to our knowledge of organic chemistry than Sir Robert Robinson. His early interests lay in the determination of the structure and the synthesis of natural products. This followed from his association with his teacher, Prof. W. H. Perkin, a master of experimental method. Robinson's classical paper on the biosynthesis of alkaloids, published in 1917, provided the guide to much of his future work, culminating in his determination of the structure of strychnine and his synthesis of the sterols. This work alone would place him in the first rank of organic chemists; but he is unique in that he, unlike his teacher, was greatly interested in organic chemical theory. During the years 1920–26 he laid the foundations of the modern theories of organic chemistry and of the mechanisms of organic reactions. The younger school of organic chemists fails at times to recognize this major contribution to their science.

On September 13 Robinson attained the age of seventy, and as tribute to his friend and former teacher Sir Alexander Todd has edited a series of essays entitled "Perspectives in Organic Chemistry". The contributors include not only his former students and collaborators, Sir Alexander Todd, Profs. Wilson Baker, E. L. Hirst, H. Erdtman, E. Schittler, Dr. J. W. Cornforth, but also many foreign friends, L. Pauling, K. Folkers, A. Butenandt, L. Ruzicka, K. Ziegler and R. B. Woodward. It would be impossible in any short review to do justice to this remarkable series of essays; each of them is in its own way masterly, and they should be read and re-read by all organic chemists. They suggest that organic chemistry is at the cross-roads. In the past two decades the techniques available to the organic chemist have been greatly refined. New methods of purification, such as paper chromatography, vapour-phase chromatography and counter-current distribution, have been developed, while increased assistance can also be obtained from infra-red and ultra-violet absorption spectra. Yet the recent reliance on R_F values and of infra-red spectra alone as a proof of identity, in the absence of direct chemical evidence, must be deplored. As Prof. Woodward points out in his brilliant essay "Synthesis", this branch of our science, apart from its intellectual attraction, has still a major function to perform. Will not these new techniques enable the organic chemist to attack more successfully the chemistry of life? Dr. Cornforth, in concluding his essay on "Isotopes in Organic Chemistry", rightly suggests that organic chemistry and biochemistry can no longer be regarded as distinct disciplines. This is well illustrated by the contributions of Dr. Folkers' "Micro-organisms in Organic Chemistry", Sir Alexander Todd's "Nucleic Acids" and Prof. Erdtman's "Organic Chemistry and Conifer Taxonomy".

We feel that all chemists will be grateful to Sir Alexander Todd for having edited this remarkable tribute to a great chemist. It is beautifully produced, and an excellent coloured photograph of Sir Robert Robinson forms a frontispiece. It is unfortunate that its somewhat high price may limit its circulation.

J. L. Simonsen

ZOOLOGY OF ICELAND

Zoology of Iceland

Four volumes (65 parts). (Copenhagen: Ejnar Munksgaard, 1937–1955.)

The publication of this ambitious work started in 1937, and by July 1956 sixty-five parts, divided into four volumes, had appeared, and the preparation of six more was announced. It will doubtless be several years yet before the end is in sight. The "Zoology of Iceland" is already of great value to zoologists working in many fields of their subject, and when complete it will be the standard work for a century or more. Its scope is wider than usual with similar faunistic surveys, for it aims at a complete description of the occurrence, range, and biology, so far as they are known, of every species of animal—terrestrial, freshwater and marine—that has been found in Iceland and the surrounding seas: a truly colossal task.

All the parts are written by authorities in their respective fields; most of the writers are Danish or Icelandic, but the editors have enlisted the help of those of other nationalities wherever desirable. The editors have also wisely ensured the widest availability of the work to zoologists by publishing it entirely in the English language.

Each part of volumes 2, 3 and 4 deals with a separate group of animals, generally an order, though in some the group is larger and in others smaller. The general plan is to start with a short historical introduction and then to provide a full synopsis of the species, giving status, records of occurrences, distribution outside Iceland, and short notes on biology. This is followed by a section of general remarks and discussion on the biology of the forms concerned and their zoogeography, and by synoptic tables. Each part concludes with a full list of references.

Volume 1, however, contains the papers of widest interest: Part 4, "The Hydrography of Icelandic Waters", by Helge Thomsen, Part 6, "The Benthonic Animal Communities of the Coastal Waters", by R. Spärk, and Part 11, "The Hot Springs, their Animal Communities and their Zoogeographical Significance", by S. L. Tuxen. The last is a very thorough account of the subject, and the author concludes that some of the members of the hot-spring fauna have probably been present for some 100,000 years because their warm environment enabled them to survive the last ice age. Indeed, he goes further and suggests that they may have survived the earlier ice ages too, and thus have perhaps been present throughout the whole of the Pleistocene period. This paper is illustrated with a number of interesting photographic plates.

When this great work is complete, no similar region of the globe will have such a comprehensive written history of its fauna. It will be an example and an inspiration to zoologists all over the world to work towards producing like surveys of the regions with which they are familiar.

L. Harrison Matthews

PHYSIOLOGY OF REPRODUCTION

Marshall's Physiology of Reproduction

Edited by Dr. A. S. Parkes. Vol. 1: Part 1. Third edition. Pp. xix+688. (London and New York: Longmans, Green and Co., Ltd., 1956.) 150s. net.

The first edition of the late Dr. F. H. A. Marshall's "Physiology of Reproduction" appeared in 1910. The second, which was published in 1922, was described in these columns as the best treatise on the subject that we have. The reviewer went on to say that "it is because it is so good and so valuable that its beneficiaries are so concerned in its further development. It must remain the best book on the subject and a memorable contribution to British scientific literature". His hope has without doubt been realized in the third edition, now enlarged to three massive volumes, of which the first appeared in 1952, and the second is now under review. A third volume, dealing mainly with the male, is still to come.

The new edition is edited by Dr. A. S. Parkes and numbers among the contributors many of those who have been responsible for the advances that have been made since the second edition. Vol. 1, Part 1, which in spite of its numerical description has appeared after Vol. 2, contains two chapters contributed by Dr. Marshall himself and in collaboration with Dr. Harrison Matthews. These give a general account of breeding periodicity and also describe cyclic changes in the lower vertebrates. About half the volume, by Dr. P. Eckstein and Sir Solly Zuckerman, is concerned with the morphology of the male and female non-pregnant reproductive tracts and provides a systematic account of the œstrous cycle in different groups of mammalia. Most of these chapters will be used for reference rather than read from beginning to end, and there is no doubt that students of reproduction will find them more up-to-date and comprehensive than any other statement about the topics with which they deal. The remaining chapter in this volume (by Prof. F. W. R. Brambell), which is concerned with the development of the ovary, the process of oogenesis, and the changes in the ovarian follicle during the course of the reproductive cycle, provides an excellent review of these perennially controversial matters.

The book remains unique for the reason that it supplies comprehensive and critical surveys of all aspects of the physiology of reproduction—something which no other single work attempts. In recent years fashion has tended to shift the focus of research to the chemical investigation of the sex hormones. Marshall's "Physiology", and especially this volume, is a reminder that, however eclectic the chemical story of reproduction becomes, its meaning is derived only from its relevance to biological phenomena, about which we understand very much more to-day than we did at the time when Dr. Marshall conceived of his gargantuan task.

P. L. Krohn

AN INDIAN HISTORY OF SCIENCE

Bijnaner Itihas (A History of Science)

In Bengali. By Sri Samarendranath Sen. Pp. xv+348+13 plates. (Calcutta: Indian Association for the Cultivation of Science, 1955.) 8*s*. Rs. 10.

THIS book is the first of a series which the author hopes to publish on the history of science. It takes the history from earliest times up to the Dark Ages in Europe and the end of ancient science. Although it is not the first book dealing with this subject to be written in an Indian language, it is certainly a far more serious attempt than any of its predecessors. As such it deserves to be considered from two points of view: that of its place in the literature of the history of science and that of its place in Indian writing.

From the former point of view it is evident that the author has drawn largely upon the writings of Sarton, Singer, Childe, etc. He frankly admits that his work is mainly based upon that of others, and reference to his bibliography will show that his sources are all in European languages. Any special interest which the book may hold for the European is thus likely to be on account of its taking a new approach to familiar problems. In fact, the author's breadth of vision is such that he rarely attempts to depart from accepted formulations, and only very rarely does his approach seem strange. It is when we consider the place of the book in Indian writing that its importance becomes apparent. The history of science is a very young child in Europe and America, but in India (at least in Indian languages) it owes its birth to Mr. Sen. Since India received independence, there has been an increasing expansion of education in the vernacular languages and a corresponding decline in the knowledge of English: this is only natural. At the same time, there has been an ever-increasing demand for technical and scientific education: if this demand is to be met, text-books will be required in the vernaculars. In view of the very wide attention which the history of science has recently attracted and of the growing belief that it is important for students of the humanities no less than students of science, the production of this book is an important landmark in Indian literature.

The plan of the book is simple. In the first chapter the author discusses the meaning of science and the relationship of science and society. He makes it clear that he is no adherent of the school which seeks a narrow fixed definition of the word and urges the need for progressive re-definition in dealing with different periods. He is also not prepared to adopt any extreme position in discussing the relationship of science and society. In the second chapter he draws upon archæological materials to outline the progress of man through the Old Stone Age and up to the Neolithic Revolution. In the third chapter the civilizations of the ancient river valleys are considered, together with the various branches of knowledge which then developed—writing, mathematics, medicine, etc. Here the author has made a bold but not altogether happy choice in describing the Indus civilization in more detail than those of Egypt and Mesopotamia. As our knowledge of the latter is so much greater and is aided by written sources, they appear inevitably to be more worthy of description. The next three chapters are devoted to an outline of Greek science from the beginnings down to the Alexandrians, the concluding two to Roman science and to the decline of ancient science and the causes for it.

We can only applaud this balanced and well-produced book, and look forward with interest to the further volumes the author has promised.

F. R. Allchin

STRUCTURAL GEOLOGY

Structural Geology

By Prof. L. U. de Sitter. (McGraw-Hill Series in the Geological Sciences.) Pp. viii+552. (London: McGraw-Hill Publishing Company, Ltd., 1956.) 67*s*. 6*d*.

THERE is no other book like this available in the English language; its appearance is as notable an event as was that of the "Einführung in die Geologie", by Hans Cloos, in 1936. The work is planned for a broad canvas, and details as well as the most prominent aspects have received careful treatment. Microstructures, minor folds, single mountains and great mountain systems are all grist to the mill. At the very least the book provides a convenient reference to an assemblage of world-wide, recent and sometimes rather inaccessible works upon most aspects of structural geology, and presents them with fair and fearless criticism; and what is much rarer, it risks a definite opinion upon most issues. But it does more, for it presents the considered views upon the architecture of the Earth of an erudite, philosophical but still active field geologist. "As a field geologist", Prof. L. U. de Sitter writes, "I tend to believe what I see more than what I read", and his readers may think that they do too. Nevertheless, what he has written will stir up argument and shake up some time-honoured but not very sound opinions held by all varieties of geologists.

There are three parts. In the first the theory of strained materials is reviewed with more mathematical analysis than is usual in most geological literature. This may lead to some floundering in a morass of equations and may encourage the reader to pass on quickly to the account of models illustrating sundry structures, only to find that there are slippery patches here too. Distortion in oolites and other rocks, cleavage, schistosity and preferred orientation are dealt with in turn. Some space is devoted to the processes of compaction of loose and water-logged sediments showing how an unstable equilibrium may be disturbed and result in a sudden and catastrophical increase in fluid pressure. A similar process is considered later as a possible source of energy to set going magmatic intrusions. Part 2 records the results of stresses in the Earth's crust which lead to the suite of faults and folds that are familiar features in most mountain ranges. Complications which ensue when vertical uplifts affect the strongly folded rocks are referred to under the heading of gravitational gliding and collapse structures. It is argued also that the thickness of competent strata has an important part to play in setting up a pattern of folds and determining the size of individuals. Folds, once formed, are reluctant to give way to a new set of forces, but ideally they should, and cases are described where such things seem to have happened. The largest features on the Earth, like the Alpine and the circum-Pacific mountain chains, come in for discussion in Part 3. Magma is injected along such lines and helps in their formation, and is a clue to the course of events which took part in producing the complicated structures which are the final result. By contrast, the nature of the areas of unfolded rocks which appear within these great mountain chains is described.

To round off the book, Prof. de Sitter trails his coat by airing his views about a history of the Earth which he makes attractive by telling us of the youthful stage when, without a heavy core, convection currents within the Earth held sway and carried continents around the surface of the Earth. Growing older, its heavy core increased in size and obstructed these lively convection currents so that the continents came to rest a long time ago, during the pre-Cambrian in fact. Since then the Earth has been provided with permanent ocean basins and continents which have not changed their position essentially, although their margins have suffered some alteration through wear and tear, which is always taking place.

The book is deplorably edited. Slips in spelling abound. The inconsistent use of sometimes English and sometimes American words, and the invention of words that are not in the English language, like 'basculate', mar the presentation. The noun 'basin' is made to masquerade as a verb. Several diagrams are reduced too much, and some stand in need of more adequate explanation. The changes introduced into the sections shown through Iranian oilfields, Fig. 133, are so radical that the figure should not be printed as if it had the authority of the late G. M. Lees.

J. V. Harrison

FUNCTIONAL ANALYSIS

Functional Analysis

By Frigyes Riesz and Béla Sz.-Nagy. Translated from the Second French edition by Leo F. Boron. Pp. xii + 468. (London and Glasgow: Blackie and Son, Ltd., 1956.) 65s. net.

THE French version of this book, the first edition of which appeared in 1952, has already become widely known, and the English translation deserves the warmest of welcomes. The senior author, F Riesz, who died earlier this year (see *Nature*, 177, 870 1956), was one of the pioneers of functional analysis, and his collaborator, B. Sz.-Nagy, has made many valuable contributions to the subject.

The book opens with an exposition of Lebesgue integration, following a method devised by F. Riesz himself. The idea is to avoid any preliminary discussion of measure theory, the integral being defined first for step functions, and then for limits of monotone sequences of step functions. Once the principa properties of the integral have been established, the reader is introduced to some of the ideas of functiona analysis, as they are exemplified in the L^p spaces these include the Riesz–Fischer theorem, orthonorma systems, linear functionals, weak convergence and weak compactness. The Stieltjes integral is also treated.

Attention is next directed to the theory of linear integral equations. The method of approximation by kernels of finite rank, introduced by E. Schmidt and developed by J. Radon, is used to prove the theorems about the Fredholm alternative. After a brief account of the Fredholm determinants, the alternative theorems are proved again, the proof now being founded on the complete continuity of the integra operators; the whole Riesz–Schauder theory is thus obtained. The authors return to integral equations again later with the Hilbert–Schmidt theory of symmetric kernels, treated as a special case of the theory of completely continuous symmetric operators in Hilbert space.

Hilbert space theory is carried as far as the spectra theorem and the functional calculus for unbounded self-adjoint operators. Other topics treated are perturbations of the spectrum, the extension of symmetric operators, von Neumann's theory of spectra sets, groups of unitary and of self-adjoint operators and the basic ergodic theorems. In Banach space theory the Hahn–Banach extension theorem and it consequences are discussed; the theory of semigroups recently created by E. Hille and others i outlined; and there is a brief account of the spectra theory of F. Riesz and N. Dunford, where the resolven of an operator is treated as an analytic function in th complex plane.

The aim of the authors is to introduce the reade step by step to the fundamental ideas of functiona analysis, rather than to plunge him straight into an axiomatic account of its abstract logical structure for example, the notion of linear functional appears in several concrete cases (the Hilbert space of function of integrable square, the L^p spaces, the space o continuous functions) before the general definition for an abstract Banach space is given. There are numerous illustrative examples, which enable one to obtain a firm grasp of what the ideas mean and how they can be used. The book is extremely readable and the translator has done his work well; anyon who wants to know what functional analysis i about would do well to begin here.

F. Smithies

Chemical Pilot Plant Practice

By Donald G. Jordan. (Chemical Engineering and Technology Library, Vol. 1.) Pp. viii+152. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1955.) 3.50 dollars.

THE opening chapter of this small book contains an interesting discussion of the general factors to be taken into account before building a pilot plant; these include, among others, cost estimation, the size and location of the plant, and the type of men required to operate it. It is also emphasized that pilot plants are not always required for checking and correcting the theories used for the design of full-scale plant, but may be used for small-scale production in order that the properties and commercial value of new materials may be studied and sufficient quantities of by-products may be obtained for the assessment of their utility. An analysis of the scale-up problem follows, and a chapter on the handling of materials on the pilot scale. In the next two chapters, various types of reactors and separation processes are discussed, and finally the important subjects of report writing and cost estimation are dealt with in detail.

Very little space is given up to theory, as it is assumed that readers are already conversant with the theoretical side; at the same time it would be unfair to describe the book as consisting of 'hints and tips'. Although these abound, they are presented as part of a reasoned discussion in which it is clear that the author is writing from practical experience. All who are concerned in any way with pilot plant are recommended to read this book, for very few will fail to derive some benefit from it.

H. E. WATSON

General School Physics

Heat and Light. By R. Stone, N. Bronner and J. Lawrence. (Grammar School Series.) Pp. ix+374. (London: English Universities Press, Ltd., 1955.) 9*s.* 6*d.*

WITH the senior science master of Manchester Grammar School as editor and part author, one former member of the staff collaborating, and another participating with advice, this excellent textbook for middle school use has the hall-mark of thoroughness and sound teaching that would be expected. It should help pupils to a real understanding of these parts of the subject, and stimulate their awareness of the application of physical principles in the world around them.

Mr. R. Stone's predecessor, the late H. S. Newbould, used to caution his younger colleagues not to try to teach too much; and there is always the temptation in elementary work to carry one's own interests to a level a little above the pupils' heads. Here the authors have not concealed their enthusiasm, but they have taken the greatest care to keep within the capacity of fifth-form boys in their explanations.

The diagrams, drawn with the clarity and simplicity of blackboard figures, are unusually good. In optics, great attention is given to ray diagrams, and this is clearly the method that the authors prefer at this stage for the solution of problems. Many teachers also may feel that algebraic formulæ are best deferred until a later stage, when they have to be repeated in any event; those addicted to their use will certainly approve the authors' analysis of the schoolboy's difficulties, and may find an answer to their own in the treatment advocated here.

G. R. NOAKES

Textile Testing

By James Lomax. Third edition. Pp. xiii+218+14 plates. (London and New York: Longmans, Green and Co., Ltd., 1956.) 30*s.* net.

THE arrangement and content of the third edition of this book are substantially the same as in the second edition. New material has been introduced in a few places in the text and, in seven pages of "additional notes", at the end. An introduction has been added. It is to be regretted that the author has not taken the opportunity of including descriptions of yarn-irregularity meters, methods of yarn inspection, or the newer automatic single-thread testers. Other important omissions are the use of the thread-crimp tester, the determination of threads per inch, cloth handle, creasability and tearing strength.

The author illustrates most of the calculations by examples worked out in detail. Such assistance is a luxury in a book of this kind. On the other hand, there is a lack of scientific and technological background, and of advice on the proper application of the methods described. In any future edition this balance should be corrected. British Standards Handbook No. 11 (to which the author frequently refers) now provides a manual for nearly all the routine work of a textile laboratory, and a modern text-book on textile testing could well be written with the aim of providing the basic information required to understand the techniques and apply them intelligently.

The book cannot be recommended unreservedly to a young student as his only guide because of a number of statements that are either inaccurate or inadequate.

H. M. TAYLOR

The Mechanical Properties of Textile Fibres

Edited by R. Meredith. (Deformation and Flow: Monographs on the Rheological Behaviour of Natural and Synthetic Products.) Pp. xii+333+4 plates. (Amsterdam: North-Holland Publishing Company, 1956.) n.p.

TEXTILE fibres are a class of technologically important materials with interesting mechanical properties: they are non-linear, strongly time-dependent and sensitive to humidity and temperature. Their various chemical structures, and the physical and chemical treatments they receive in processing and manufacture, result in many variations on the general pattern of behaviour.

Dr. R. Meredith and his co-authors Dr. L. Peters and Mr. H. J. Woods have written a welcome book in which they describe the mechanical properties of the various fibres and report the current position in the interpretation of those properties in relation to fibre structure. Cellulose, protein and synthetic fibres are discussed in separate sections which follow similar patterns for ease of cross-reference. There are chapters on structure, stress relaxation and creep, load-extension curves and on dynamic properties, each section ending with a chapter on properties which have received attention because of their practical importance: the strength of cellulose fibres, setting effects in keratin fibres, and resilience and creasing of synthetic fibres. Separate chapters are devoted to reaction-rate theory in two sections, and the theory of linear viscoelasticity is treated in connexion with stress relaxation and dynamic properties. There is a comprehensive bibliography.

IRRADIATION LABORATORY OF THE BRITISH INSULATED CALLENDER'S CABLES, LTD., RESEARCH ORGANIZATION

By DR. R. M. BLACK

IT is now fairly well known that, when polymeric materials are exposed to high-energy radiation in atomic piles or from sources of beta- or gamma-radiation, they undergo profound changes in their physical properties. These changes are the result of a series of intermolecular reactions or rearrangements induced by the ionization and free-radical formation phenomena associated with the absorption of the radiation.

A study of the effects of irradiation of vinyl polymers and related hydrocarbons has shown that the radiation chemistry of the process involves a number of fundamental chemical changes: (*a*) formation of carbon-carbon bonds between the molecules accompanied by the liberation of hydrogen to give a three-dimensional polymer network; (*b*) formation and hydrogenation of carbon-carbon double bonds; (*c*) molecular degradation by fracture of the main polymer chain by a disproportionation reaction resulting in a product of lower average molecular weight; and (*d*) fracture of chemical bonds in the side-chains or branches of the polymer, with the production of low molecular weight hydrocarbons.

The balance between these reactions is not the same in all polymers and, in practice, it is found that either cross-linking or molecular degradation predominates, depending upon the molecular structure. Thus, dielectric materials can be classified into two categories: those in which cross-linking predominates (such as polyethylene, polystyrene, polyvinyl chloride and the silicones) and those in which degradation predominates (such as polyisobutylene, 'Perspex', polytetrafluoroethylene and cellulose). Some materials, by virtue of their chemical structure and the possibility of energy transfer and resonance effects, are more resistant to the effects of radiation than others. Polymers which contain aromatic side-chains (phenyl groups) are particularly resistant to radiation.

The behaviour of polymeric dielectric materials on irradiation is of interest for two main reasons. First, it may prove possible, by irradiation, to induce changes in the structure of the material which cannot be achieved by other methods and which will result in a product with improved properties. Second, if the material is to be used in a locality in which it will be subjected to constant irradiation, such as the biological shield of a nuclear reactor, the expected service life and a knowledge of the changes in electrical properties likely to take place are important considerations.

In order to investigate and, if possible, to exploit the properties produced in dielectric materials on irradiation, the Research Organization of British Insulated Callender's Cables, Ltd., has recently established an irradiation laboratory. This laboratory is equipped with a 2-million volt Van de Graaff electrostatic particle accelerator supplied by the High Voltage Engineering Corporation of Cambridge, Massachusetts, which serves as a versatile source of electrons, gamma- or X-rays, positive ions and neutrons. In addition, there is available a comprehensive radiochemical laboratory, equipped with a wide range of counting equipment and radioactive isotope sources, for the development of new techniques for testing and process control.

The Irradiation Laboratory is divided roughly into three parts by the central, two-story, radiation block. The latter consists of a target room on the ground floor with the generator room situated immediately above it. The walls of the target room are of concrete, 3 ft. in thickness, to prevent hazardous amounts of radiation entering the adjoining laboratories, and entrance to the room is by means of a safety door, connected to an interlock system, and a concrete labyrinth.

The target room is of sufficient size to enable a variety of irradiation experiments involving the use of conveyor belts and pulley systems, etc., to be carried out and, in addition, houses the pressurizing gas supply (carbon dioxide and nitrogen) for the generator.

The generator itself, which is designed to project a beam of electrons or positive ions vertically downwards, is installed in the room above, access to which is obtained by means of a spiral stairway from the target room. As the radiation intensity is consider-

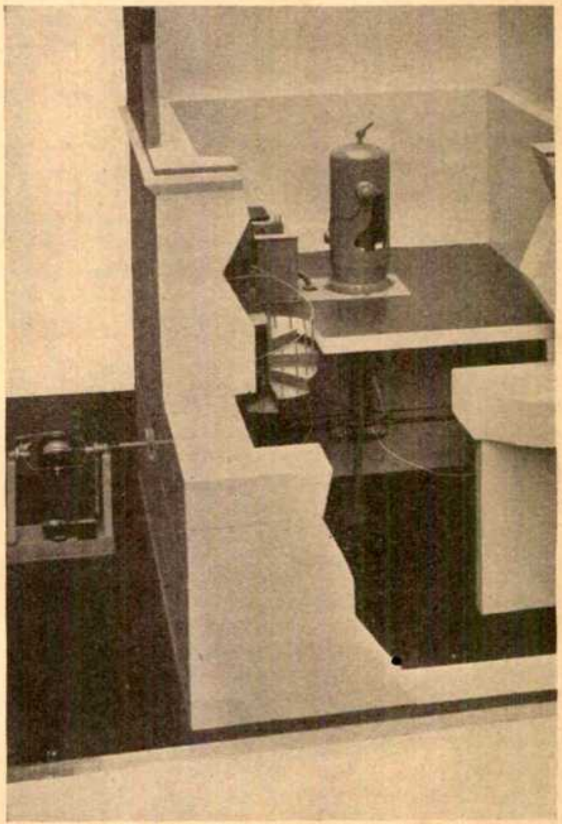

Fig. 1. Model of irradiation block, showing scanning assembly

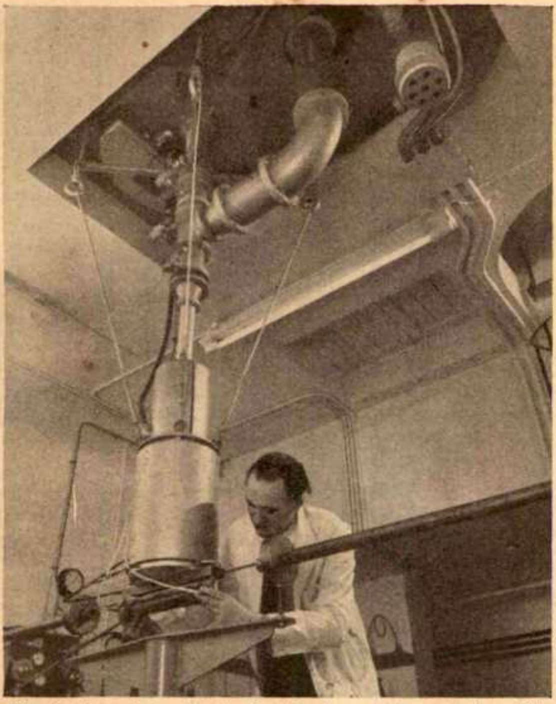

Fig. 2. Scanning unit, showing the base of the generator with diffusion pump and vacuum system

ably lower than in the target room, the thickness of the generator room walls needs to be only 2 ft.

The water supply for the laboratories and for the generator is provided by two large tanks situated on the roof of the radiation block, and the necessary pressure for the cooling system of the Van de Graaff accelerator is obtained with boost pumps.

The generator block is flanked on both sides by laboratories which contain the control panels of the generator and various types of cable-handling machinery; and they are equipped for carrying out the various evaluation tests necessary and investigations upon the irradiated products.

Of the irradiated dielectric materials so far studied, one of the most interesting is polyethylene, as this polymer is cross-linked by high-energy radiation to give a polymer network which has a greatly reduced solubility in hydrocarbon solvents and which exhibits rubber-like elasticity at higher temperatures (greater than 115° C.) instead of melting. This elastic behaviour and non-flowing property at high temperatures would suggest that irradiated polyethylene has considerable possibilities as a high-temperature dielectric and, while the chemical changes accompanying the cross-linking tend to render the polymer more susceptible to thermal oxidation, investigation has shown that this can be reduced by the prior incorporation of a suitable antioxidant.

Radiation effects such as cross-linking and degradation are not, of course, limited to materials of high molecular weight. Hydrocarbons such as hexane and decane show a similar behaviour, and a study of simple materials is beginning to throw light upon some of the mechanisms of electrical breakdown phenomena. Similarities exist between radiation effects and the ionization effects which sometimes occur in high-voltage equipment under conditions of electrical stress. The well-known phenomenon of waxing or 'cheese' formation in some types of solid cable is only another form of cross-linking by electron bombardment, while the radio-oxidation which takes place during the irradiation of materials in the presence of air bears a direct relationship to the stress-ageing effects encountered in insulating oils contaminated with oxygen.

High-energy particle accelerators serve not only as a source of radiation for industrial processing but also as valuable laboratory tools for fundamental research. There is no doubt that the new techniques which have arisen during the development of atomic energy in the past ten years will find increasing application in the solving of technical problems which arise in the electrical industry.

PROPERTIES AND USES OF FERRITES

CONFERENCE IN LONDON

IT is difficult to-day to name a branch of the sciences or a field of industry or of human endeavour in which electronic devices play no part. During the past twenty-five years the electronics industry throughout the world has expanded at a very great rate, and new discoveries can be of major commercial value. It is not surprising, therefore, that reports ten years ago of the successful preparation of new magnetic materials with obvious applications in electronics and light electrical engineering were received with marked interest.

The use of ferromagnetic materials in coils and transformers had hitherto been restricted to the low-frequency region because of eddy-current losses in the metallic ferromagnetics available. Some improvement had been achieved by the use of fine metallic powders in a non-magnetic matrix—'dust cores'—but while eddy-current losses were thereby reduced, hysteresis losses were usually considerably increased. In 1946, some results were announced of work carried out under great difficulties at the Philips Laboratories in Holland during the German Occupation. The late Dr. J. L. Snoek and his colleagues had succeeded in preparing oxide materials with strong ferromagnetic properties, high electrical resistivity and low hysteresis loss. These materials were ferrites (in fact, mixed crystals of different ferrites) which had first been prepared by Hilpert in 1909; but Hilpert's materials, though ferromagnetic, had shown high losses in the presence of alternating magnetic fields and low permeability, and had no commercial value. Snoek's materials had considerable value and were soon made available commercially by Philips under the name of 'Ferroxcube'; later they were manufactured in the United States under the trade name 'Ferramic'.

The engineer was reasonably content, at first, to devote his skill and ingenuity to the use of the available materials, but the physicist and the physical chemist found much that was perplexing, particularly in the magnetic behaviour of these new ferrites. Their chemical composition was known to be of the form MO, Fe_2O_3 where M is a divalent metal, and the crystal structure was that of the mineral spinel, $MgAl_2O_4$; but little else was certain. In 1948, a major contribution to the explanation of the magnetic properties came from Prof. L. Néel, who introduced the term 'ferrimagnetism' to describe these properties which he showed could arise from the subdivision of the magnetic moments in the material into two groups. In each group or sub-lattice, the moments were aligned parallel, as in ferromagnetic materials; but it was assumed that the moments of the two sub-lattices were oppositely directed, so that the observed macroscopic magnetic moment was not the sum of the individual moments, but the difference of the moments of the two groups of ions.

Since 1948, ferrites have been the subject of a vast amount of work, both on fundamental theory and experiment and in practical application; and so nearly a thousand scientists and engineers from more than a dozen countries gathered in London at the Institution of Electrical Engineers, during October 29–November 2, to review and to discuss some of the investigations.

In an introductory lecture the vice-president of the Institution, Dr. Willis Jackson, gave a detailed review of the development of ferrites up to the present date and surveyed the background to the conference. The meeting was thereafter divided into sections, each of which covered a different aspect of the very broad field of study. Each session of about two and a half hours followed roughly the same pattern. Pre-prints of the papers had previously been sent to those attending the conference, and authors were allowed merely a short time for the formal presentation of their work. The major part of each session was therefore available for general discussion, which was always interesting, sometimes stimulating and occasionally heated. It would not be feasible to comment upon all the papers presented or to attempt a résumé of the many discussions, particularly as two sections were often run concurrently during the last three days of the meeting. The subjects covered can best be outlined in general terms, and reference made to only a few contributors in each section.

Fundamental properties and processes in ferrites were discussed under Section A, which was subdivided into sessions on the preparation and general chemical and physical properties; magnetic spectra; molecular interactions; magnetic properties in steady and slowly varying fields; and the properties of new oxide magnetic materials. A review was given by A. J. E. Welch (Imperial College of Science and Technology, London) of the chemistry and crystal structure of ferrites and other magnetic oxides, while in the session on magnetic spectra J. K. Galt (Bell Telephone Laboratories) discussed the problem of losses in ferrites with particular reference to his examination of domain wall movements by the use of 'picture frame' single crystals in which a single wall was studied. The several earlier contributions made by G. T. Rado and his colleagues at the Naval Research Laboratory, Washington, D.C., to the study of the frequency-dependence of initial permeability were briefly summarized and extended in a paper on the effect of magneto-crystalline anisotropy upon the magnetic spectra of magnesium iron ferrites. R. Nathans (Brookhaven National Laboratory) reported the results of a neutron diffraction study of ferrites of the magnesium manganese system. Precise crystallographic data were obtained, including the distribution of the manganese ions between the tetrahedral and octahedral lattice sites. The power of this technique was very apparent, and it is to be hoped that similar investigations with other ferrite systems will be made.

The final session in this section included contributions by E. W. Gorter and his colleagues, of the Philips Laboratories, on oxide magnetic materials with hexagonal crystal structures, and by F. Bertaut and R. Pauthenet (Grenoble) on ferrimagnetics with the garnet structure having the general formula $5Fe_2O_3$–$3M_2O_3$.

It is significant that the second largest section of five sessions, with seventeen contributed papers, was that dealing with the theory and applications of ferrite materials at microwave frequencies. With the increasing importance of microwave techniques much effort has been devoted to measuring the properties of ferrites in wave-guide circuits and to finding, usually empirically, ferrite compositions with the most suitable properties for application in microwave components. What is the effect upon an electromagnetic wave in a guide when it meets a magnetic material that has a high dielectric constant (10–20) and a permeability which is, among other things, dependent upon the direction and magnitude of the applied magnetic field? Analytical solutions are usually reached only after great labour, and the papers in this section might be said, in general, to be contributions to the experimental answer to this question.

The section was opened with a paper by P. J. B. Clarricoats, A. G. Hayes (both of the General Electric Co., Ltd.) and A. F. Harvey (Radio Research Establishment, Malvern) which reviewed the general properties of ferrites at microwave frequencies and dealt briefly with the various types of components in which ferrites are used. A feature of the printed paper which many workers will appreciate is its extensive bibliography with 195 entries. The second session was devoted to microwave theory and measurements; it included contributions by I. G. Macbean (General Electric Co. Ltd.) and by R. A. Waldron (Marconi's Wireless Telegraph Co., Ltd.) on the measurements of permeability tensor components using resonant cavity techniques. Three sessions on microwave properties and applications followed. The Faraday rotation of the plane of polarization of an electromagnetic wave by a magnetized ferrite formed the basis of (*a*) the measurements reported by R. Derry and M. S. Wills (Royal Naval Scientific Service) using nickel ferrites and ferrite aluminates; (*b*) the rotation isolator described by P. E. Ljung (Sweden) for use in the 6 cm. wave-length region; (*c*) the isolator for the 8–9 mm. region produced by Dr. Elizabeth Laverick and Miss Ann Rivett-Carnac (Elliott Bros.); and (*d*) the 45° rotation isolator discussed by A. Langley Morris (Malvern). A. G. Fox reported on several of the current research projects of the Bell Telephone Laboratories, including the use of the permanent-magnet material 'Ferroxdure' (mainly $BaFe_{12}O_{19}$) for giving broad-band properties to a circulator used in the 3-cm. wave-length region.

Section C of the conference was devoted to the theory and application of ferrites which exhibit almost rectangular hysteresis loops. J. B. Goodenough (Lincoln Laboratory, Massachusetts Institute of Technology) examined the various factors influencing the shape of B/H loops, the coercivity and the permeability of the materials, while O. Eckert (Germany) described the occurrence of constricted loops in ferrites containing cobalt oxide and showed the extent to which this property was affected by heat treatment in the presence of a magnetic field. Other contributors dealt with the applications of square-loop materials in digital computors ((B. Bambrough (Decca Radar) and W. Renwick (Cambridge)) and in data-handling systems (E. P. G. Wright (Standard Telecommunication Laboratories, Ltd.) and C. J. Quartly, A. L. Cain and R. W. Clarke (Mullard)), while W. Six and R. A. Koolhof (Philips) discussed the importance of the high-speed switching which can be carried out with ferrite materials, particularly when used in combination with transistors. Applications included electronically controlled telephone exchanges and an automatic reservation system for airline companies.

Section *D* of the conference was concerned with the application of ferrites to radio and television and included papers by R. H. C. Morgan (Mullard, Ltd.) and V. A. Jones and G. Campbell (Plessey Co.). Section *E* was devoted to carrier-frequency applications; in a review of the properties and general field of application to transformers and coils of high *Q*-factor and stability, W. F. Glover and S. E. Buckley (Standard Telephones and Cables, Ltd.) showed that ferrites can have distinct advantages over other materials at operating frequencies greater than 30 kc./s.

During the meeting there was an exhibition of some of the equipments and devices referred to briefly above. There were some thirty or forty exhibits, ranging from examples of ferrites fabricated into a wide variety of shapes and sizes through the often complicated wave-guide units involving ferrite isolators, attenuators, circulators and modulators to the simple ferrite rod aerial. To the worker in a limited field, the exhibition gave a rapid and striking picture of the wide range of application of the material the conference was discussing.

In the five days of the meeting nearly sixty papers were read which will be published with synopses of the discussions in the *Proceedings of the Institution of Electrical Engineers*, during 1957. The Institution is to be congratulated upon its decision to hold such a meeting. It was undoubtedly most successful and a tribute must be paid to its smooth and courteous organization; in particular, the strict adherence to the stated time schedule excited the admiration and envy of more than one of our overseas visitors.

It would be out of place for the writer of a review of this nature to comment critically upon any of the papers presented, but it is hoped that a general observation may be allowed. The number of scientists and engineers attending the meeting was striking testimony to the importance attached to ferrites. Although British workers were well represented as contributors in those sections dealing essentially in measurements and in applications using materials of the standard ferrite type, it does seem significant that, of the nineteen papers presented in Section *A*, only eight were from British workers and eleven, including most of those on fundamental processes and new materials, came from overseas visitors. Yet, as the conference made abundantly clear, there is much fundamental knowledge yet to be acquired.

K. J. STANDLEY

DECAY OF PLANT LITTER

IN opening the series of papers under this title at a joint session on August 31 of Section K (Botany) and Section K* (Forestry) at the meeting of the British Association at Sheffield, Dr. J. G. Boswell described observation which had been made on the chemistry and microbiology of some natural soils in the neighbourhood of Sheffield and on similar soils in northern England and southern Scotland. The local areas included the Ringinglow Bog, the surface vegetation of which is largely *Eriophorum* spp., Lady Canning's Plantation containing *Pinus sylvestris* and *Sorbus aucuparia* with *Deschampsia flexuosa* and *Galium saxatile* in the field layer, and Ladies Spring Wood with *Quercus petraea* and *Betula pubescens*. Fractionation with solvents showed that the ligno-cellulose residue from the peat of Ringinglow Bog contained 25 per cent of the total acidity and in the form of strong acids. The humus from the podsol of Lady Canning's Plantation had a lower total acidity than that of the *Eriophorum* bog in spite of a lower *p*H value, and 55 per cent of the total acidity was located as strong acids in the ligno-cellulose complex.

Microbiological examination showed that there existed in all the soils a group of active protein decomposers, but that from Ringinglow Bog nitrifiers and nitrogen fixers were never isolated. The soluble nitrogen present in this soil was in the form of ammonia, and this was a limiting factor in cellulose decomposition by fungi since while species of a number of genera, *Cephalosporium*, *Pullularia*, *Cladosporium*, *Trichoderma*, *Aspergillus* and *Penicillium*, were isolated, those which in pure culture would decompose cellulose did so only when nitrogen was supplied in the form of nitrate. The humus layer from Lady Canning's Plantation contained a number of sugar-fermenting bacteria of which the most important was a species of *Clostridium* which fixed nitrogen in pure culture, the activity being confirmed by the use of nitrogen-15. Four genera of fungi capable of decomposing cellulose were isolated, of which a species of *Aspergillus* was by far the most active.

Dr. Scurfield had examined the distribution of *Holcus mollis* and *D. flexuosa* in Ladies Spring Wood in relation to the structure of the soil profile. C/N and C/O ratios of the horizons of the profiles showed that with increasing depth, the residue under *D. flexuosa* becomes poorer in nitrogen although with an unchanged oxygen content, while under *H. mollis* the residue becomes progressively richer in both nitrogen and oxygen. The *D. flexuosa* profile contains nitrogen only in the form of ammonia, but under *H. mollis* both ammonia and nitrate are present. This, together with the facts that nitrogen-fixing bacteria appear to be more abundant under *H. mollis* than under *D. flexuosa* and that the plants of the former have a nitrogen content about 50 per cent greater than those of the latter, suggests that nitrogen relationships are an important factor in profile development.

The wide survey of soils from the northern parts of Britain amplified the observations recorded above. Further correlations were made between the E_5 potential of the soil, the activities of the nitrifiers and cellulose-decomposing bacteria, and the nature of the surface vegetation. A very widespread distribution of the nitrogen-fixing species of *Clostridium* was found.

Dr. J. Webster read a paper entitled "The Grass withereth". He pointed out that although the process of decay had hitherto been extensively studied in soil and composts, there was little published information on the succession of organisms which colonize plant remains before they are incorporated into the soil. The colonization of flowering stems of cocksfoot (*Dactylis glomerata*) by fungi was described. About two hundred species of saprophytic fungi had been collected on cocksfoot in three localities near Sheffield. Among the more common fungi found were: (1) *Cladosporium herbarum*, *Epicoccum purpurascens*, *Alternaria tenuis*, *Leptosphaeria microscopica* and *Pleospora vagans*, which were among the first fungi to fruit on moribund tissues. Although present for a limited period on lower internodes, they only persisted for long periods (up to a year) on the upper internodes. (2) *Leptosphaeria nigrans* and *Mollisia palustris* formed fruit bodies on the basal internodes within the tussock during the summer following flowering. (3) *Helminthosporium hyalospermum* and *Tetraploa aristata* also appeared at the tussock base with *L. nigrans* and *M. palustris*, but continued to fruit throughout the following winter and the second summer after flowering on collapsed stems. (4) *Acrothecium* sp.: confined to the lower internodes during the first few months following flowering. (5) *Selenophoma donacis* and *Mycosphaerella recucita* fruited on the upper internodes during the summer following flowering. These fungi were common on other grasses, and work by Mr. H. J. Hudson has shown that on *Agropyron repens* their distribution paralleled that on cocksfoot. Isolations from *Agropyron* stems also showed that the distribution of the mycelium of these fungi resembled closely the distribution of fruit bodies.

In analysing the distribution patterns further, evidence was presented that the water content of the stems was an important factor controlling distribution. Determinations of the water content (as percentage dry weight) showed that the value for the upper internodes frequently fell below 15 per cent, which was probably a limiting value for mycelial growth, while the value for lower internodes was consistently high. The water-content gradient could be destroyed by cutting stems down and placing them on the ground. This results in an upward spread of fungi in groups 2, 3 and 4 (above), and a more rapid disappearance of fungi in group 1. There was evidence, however, that other factors were important.

Dr. P. W. Murphy described the role of "Soil Acarina" in the decomposition of leaf litter. The organic detritus of the forest floor consists of stems, branches, roots, bark, fruits and seeds together with the remains of shrubby and herbaceous vegetation. The Acarina often occur in large numbers in these remains, and field observations and culture experiments have shown that certain mite species, especially the Oribatoidea, feed on leaf litter. In laboratory cultures the amount of leaf material ingested is dependent upon tree species, moisture content of the leaves and certain unknown factors, some of which may be concerned with the microfloral and microfaunal populations of the litter. Concerning the first, it is known that certain plant species show well-marked tendencies to form mull or mor, and the leaf comminuters among the fauna show a preference for mull-forming plants. For example, when cultures of *Steganacarus magnus* (Nic.) are provided with *Fraxinus*, *Betula*, *Pseudotsuga taxifolia* (Poir) and *Pinus sylvestris* L., a series chosen to represent broadleaf and conifer species which have reputations for 'rapid' and 'slow' decomposition respectively, a definite preference is shown for broadleaf as opposed to conifer litter, and ash to birch. An exception to the above situation was found in the case of *Nothrus sylvestris* Nic. cultured on *Calluna vulgaris* Salisb. and *Picea sitchensis* Trautv. and Meyer, when there was very little difference in preference, and quite large quantities of *Calluna* were ingested. This result is rather unexpected in view of the nature of *Calluna* litter, and the length of time it remains apparently little altered under natural conditions. The reasons for these preferences are not at present clear, but there is some evidence that the physical properties of the litter are of importance.

At present little is known about the metabolism of these creatures, and thus the chemical changes taking place during the passage of leaf material through the gut. The average size of the leaf particles in the excrement was about 5μ × 3μ, and it is evident that apart from any chemical transformations the part played by these mites in the physical disintegration and comminution of the leaf litter is of a high order.

The excrement is deposited usually in the form of round or cylindrical pellets, and it is probable that they provide sites for further decomposition by plants and animals. With certain 'humus forms', moder, for example, these pellets are very numerous, and indeed in the *H* layer of protorendzina soils practically all the organic matter may be present in this form. In mull soils, on the other hand, although mites may be very numerous, the amount of recognizable excrement elements is not great, and it is likely that the further decomposition stages are much more rapid under these conditions.

Dr. J. D. Ovington read a paper on "The Importance of Litter Breakdown in the Woodland Ecosystem". The formation of a surface layer of organic material is a characteristic feature of many British woodlands. In some woodlands, particularly of hardwoods, the litter may almost completely disappear before the next leaf-fall; in others, usually but not always conifers, the litter forms a permanent cover over the mineral soil. The amount and type of humus formed varies considerably, depending upon many factors, and has been regarded as an indication of the ecological status of the woodland, particularly from the point of view of nutrient supply and biological activity.

The litter is derived from a variety of sources, for example, from the tree canopies and roots, from the associated shrubs and ground flora and from the forest animals. Because of the dynamic nature of the woodland ecosystem the relative amounts of litter contributed by each of these may vary considerably from woodland to woodland and also at different stages of development of the same woodland.

From studies in an age series of Forestry Commission plantations of *Pinus sylvestris* grown at Thetford Chase, it has been possible to determine the annual fall of litter from the trees as cone, branch and leaf material. At forty-seven years of age the litter fall from the trees is about 5,000 kgm. of oven-dry matter per hectare or about twice the total weight of litter over the forest floor. When heavy thinning and pruning take place the annual deposition of litter may increase to 15,000 kgm. of dry matter per hectare and branch material forms a much greater proportion of the litter. In all, the total oven-dry weight of litter falling from the crop of *Pinus sylvestris* during fifty-five years of afforestation is approximately 300,000 kgm. per hectare, about half of this being leaf material.

The contribution of the ground flora to litter formation varies considerably, depending upon the density and nature of the tree crop. In old plantations the ground flora may be heavier than the weight of leaf carried on the trees, so that the death of the shoots of the associated herbs results in a significant annual contribution to litter formation.

Considerable amounts of plant nutrients are contained in the organic matter falling each year in woodlands. Since the accumulation of litter after forty-seven years of afforestation with *Pinus sylvestris* only equals the litter fall for two average years, it is evident that a large proportion of the plant nutrients has been released into the ecosystem by the decomposition of the litter. The release and circulation of plant nutrients may be much greater in an actively growing woodland with a mor humus layer than in a slower growing woodland having a mull humus. A more dynamic approach to litter formation in woodlands by studying the diverse aspects of nutrient turn-over is needed and should be closely linked with the biological activity of the micro-flora and fauna.

J. G. BOSWELL

VIGILANCE

A SYMPOSIUM on "Vigilance—the Nature of Alertness and the Problem of its Maintenance during Long Spells of Work" was held by Section J (Psychology) of the British Association during the recent meeting there. Dr. N. H. Mackworth (Medical Research Council Applied Psychology Research Unit), the opening speaker, defined vigilance as a state of readiness to detect and respond to certain specified small changes, occurring at random time-intervals, in the external environment. In real life, the problem was to discover why people failed to notice and act on a signal which they were normally quite able to detect. Although they knew what they were looking for, they did not know when to expect this signal. Experimentally it had become customary to measure inspection performance by considering (1) the average number of signals neglected over a given period, or (2) the intensity to which a given signal had to be raised before it was reported.

The main factors in vigilance were either environmental or motivational. The environmental factors included the work situation as well as the general surroundings.

The environmental variables in the work situation were mostly concerned with the dimension of time. For example, Deese[1] had demonstrated how the probability of detection depended on the frequency of signals per hour. Baker[2] had shown that the uneven spacing of signals along the time scale was of even greater importance. This unpredictability in time was thought to carry more weight than any other single environmental factor in causing a loss of alertness during prolonged work. Long working spells were known to be a further factor; Wyatt[3] had demonstrated this in industry, as had Mackworth[4], Broadbent[5], Baker[2], Whittenburg and others[6], and Adams[7] in the laboratory. According to circumstances, alertness began to deteriorate anywhere between a few minutes to one hour from the start of the spell, but usually about half an hour from the beginning. The duration of the signals was also of importance in some cases[7]; but Saldanha[8] had demonstrated that there could be a marked decline in accuracy of response even when the signal remained available until response was made. Aspects of the working situation not yet studied in any detail were the possible effects on alertness of having to neglect many unwanted signals. Regularity in the temporal spacing of wanted signals helped performance; but perhaps regularity in the unwanted signals might hinder it. Little was also known about the effects of systematically increasing the frequency of unwanted events.

The environmental factors in the general surroundings that reduced watchfulness were continuous noise[9], high atmospheric temperatures[10] and isolation[11].

The motivational variables were less clear although of equal importance; the increased motivation of immediate knowledge of results could keep vigilance at its initial level for two hours[4]. Reducing motivation by lack of sleep gave a marked increase in the number of unreported signals during a 45-min. test[12].

Mr. E. Elliott (Admiralty Research Laboratory) discussed the change of the effective threshold during the day. The classical threshold for detecting a stimulus was the level at which the stimulus was detected on half the presentations, but this assumed the optimal conditions of expectancy and perception. In real life, such optimal conditions were not present and men did not detect the stimulus at the classical level but at some higher level which could be called the effective threshold. This was measured by giving the subject at random intervals an auditory signal the strength of which was equal to the classical threshold for that subject. The effective threshold was regarded as zero decibels if the subject gave a response at that level. If he did not detect this signal it was repeated about 30 seconds later one decibel louder than the classical level. If still undetected, the signal was repeated after about the same time-interval two decibels above the classical level, and so on until the signal was detected and reported by a key being pressed. The effective threshold was the amount the signal had to be increased above the classical threshold for detection.

This ascending series was given at intervals about ten times during the two-hour test. This technique was used for examining effective auditory thresholds in six subjects tested daily for three weeks. In the morning they were given ten measurements of effective thresholds in two hours, and in the afternoon they were given ten signals per minute each 1 decibel above threshold. The average effective threshold was found to be about 4 db. above the classical threshold; 10 per cent of the time it was less than 1 db.; but 10 per cent of the time it would exceed 8 db. It was found that there was a large improvement in the effective thresholds for each subject (as measured in the morning) as time went on, but the improvement did not affect the 5–10 per cent period during which effective thresholds were 8 db. or worse.

Other subjects were first tested only by the morning procedure and then the faster presentation of the afternoon was added later. This improvement in the morning results seemed to depend on the presence of the afternoon tests, suggesting a transfer effect. However, the commissive error rate was roughly doubled by the introduction of the afternoon sessions. In fact, the subjects were trained by the frequent but weak signals of the afternoon to listen down to the noise itself.

Thus when a high probability of detection of a signal in noise was required, a high commissive error rate should be encouraged. But the really serious problems of vigilance were related to the larger peaks in effective threshold curves, when the signal strength had to be 8 db. or more above the classical threshold to be detected. These peaks could lead to very expensive mistakes and dangerous accidents.

When a man was asked to do a vigilance task, he had to stop his normal behaviour of scanning rapidly from one set of stimuli to another and concentrate on one set only. It was desirable that his effective threshold for these stimuli should be very low, although his natural living threshold might be very high. It was therefore necessary to study normal vigilant behaviour outside formal test periods.

Mr. D. E. Broadbent (Medical Research Council Applied Psychology Research Unit) discussed the relation between the failures of the vigilant man who was only watching for an occasional signal to which he had to react, and those of the active man who was keeping up a steady stream of activity which had to be related to random changes in his environment. There was considerable evidence that failures in perception could occur with the active job just as with the passive one, and lead to poor performance or accidents. For example, the studies by Saldanha[8] had demonstrated that in accurately setting a Vernier gauge by means of a small handwheel, less accurate settings were being accepted after only 15 min. The accuracy with which a man could keep a pointer on a mark by turning a handle at a constant speed had been investigated by Siddall and Anderson[13]. Again, the errors became greater as time went on. In both these active tasks there was deterioration in performance, just as there was in the passive vigilance tasks.

Other workers had also shown that continuous activity did not maintain alertness in a passive vigilance task. Moreover, Adams[14] had reported that a rest pause was not so helpful to performance at an active task when the rest was spent watching someone else do the work, as when it was taken right away from the work.

It was therefore clear that failure of observation was an important element in active as well as in passive tasks. This suggested that active tasks could be usefully employed to study perceptual failure. In self-paced tasks the speed of response to a signal depended on the probability of that signal. Although the average rate of work might remain the same, there might be an increased unevenness in response shown by pauses and spurts in the activity. It seemed likely that these irregularities in performance represented fluctuations in perception and that similar fluctuations might occur in a pure vigilance task. A brief signal might occur during a brief failure of attention and therefore be missed. If, however, the signal were prolonged or repeated it would exceed the moment of failure and so be detected.

In addition to its considerable theoretical interest, vigilance was also of great practical importance, particularly as regards accident prevention.

Dr. D. H. Irvine (Army Operational Research Group) discussed vigilance in industry in relation to machine-minding and to inspection tasks, and also touched on the reliability of clinical judgments. He pointed out that the signal to be identified might be very brief, or machine paced, or it might persist until attention was paid to it. In the latter case, the signal might become more urgent as time went on, as with the warning light indicating to a motorist that his oil was low, or it might remain static, as with many inspection tasks, where the operator could take his own time to decide whether each item was faulty or not.

Inspection tasks might involve a yes/no decision, where the faulty item had to be identified and rejected, or they might involve grading into classes, or finally, they might involve accurate determinations of measurements along an apparently continuous scale. This visual inspection was affected by factors of vigilance, subjective judgments and decision taking.

Several experiments had been carried out on the variations of subjective judgments between one person and another, even when these people were experts in their own field. Moreover, they varied widely in their judgments on the same materials repeated on two successive occasions. Many of these experiments concerned clinical judgments of disease, since this was a field where the single opinion of an expert could be vitally important. This variability in diagnosis had been extensively surveyed in the examination of X-rays by experts[15–17]; the experimenters found that the use of standards reduced the variability, and that reduction of the number of possible categories also improved consistency. They recommended that for anything as important as a medical opinion at least two examinations of the material should be employed.

One of the major difficulties in investigation of inspection work in industry was the difficulty of finding out how many potential rejects were missed by the operator. Dr. Irvine had carried out an experiment in which subjects were asked to grade pharmaceutical ampoules, first for impurities, and secondly by the nature of the impurities, and each subject graded the ampoules four times, while the batch of 200 ampoules was graded by 24 different subjects, and also 32 times by the author. There was considerable variability in the grading, but it appeared that accuracy of grading improved as the results for many inspections were pooled. As with the clinical material, where high accuracy was essential, it appeared that the same material should be examined several times, if possible by several people.

This experiment also showed that the rejection-rate depended on the batch size; that is, a higher rejection-rate was obtained when the material was examined in two sessions of approximately half an hour each, than when it was all examined in one session. There was no correlation between the time each person took to complete the examination and the reject rate.

Mr. D. Wallis (Admiralty) emphasized some of the more important aspects of the papers. He pointed out that when signal frequency was increased, performance was improved in terms of probability of detection; indeed, the percentage success rose from about 40 to 90 per cent. But the absolute number of signals missed remained about the same, that is, 4 per hour, in the experiment under discussion[1]. Thus, if missing a signal was due to a fluctuation of attention, then these brief but serious lapses might be thought to occur at the same rate whatever the speed of signal presentation.

Mr. Wallis also saw a wide application of the technique described by Mr. Elliott, as this enabled an investigator to sample the precise level of vigilance throughout lengthy periods.

Among the various methods of improving performance in vigilance or inspection tasks the most effective in practice was the use of two operators at the same time, since the lapses suffered by two individuals were uncorrelated in time. In a recent study, Mr. Wallis had found that detection probabilities could be doubled by this approach. There was also the possibility of transfer from tasks specially designed to maintain vigilance to the actual task. Finally, there was the possibility that some people who liked to be quiet and alone might be better at vigilance tasks that require this than would more extroverted people.

Dr. P. Bakan (U.S. National Science Foundation) discussed his experiments on vigilance[18]. The occurrence of performance decrement over time was a result of an increase in the effective threshold for the discrimination required for the task. Repeated effective threshold measurements for the detection of occasional brighter flashes had shown that the required increase in intensity had to be raised after 15 min. Variables related to sleep were also related to a loss of vigilance in performance tasks. Monotonous environments might produce either of these states, while amphetamine sulphate could counteract them. Moreover, physiological changes such as electroencephalogram changes and reduction of muscle potentials were common to both states. However, the subject in a vigilance task would usually make efforts to keep awake by self-generated stimuli, for example, the characteristic increase in restlessness, singing or day-dreaming. It was important also for the experimenter to try to raise vigilance by introducing external stimuli in order to avoid a state of sensory deprivation[19]. Such external stimulation could be irrelevant to the particular vigilance task, yet had to be compatible with it.

Mr. D. C. Fraser (Institute of Aviation Medicine) said that three conditions were needed in a vigilance task: (1) the presence of neutral signals which had to be disregarded but throughout which the significant signals were randomly interspersed; (2) stress conditions were also required in terms of speed, load, duration, etc.; (3) knowledge of results had to be minimal. Tests of effective threshold were therefore of a different nature from the classical vigilance test. Two kinds of vigilance had been found, the alertness needed throughout a long test to detect the occasional significant signals among many other slowly presented signals, and that needed in a short test for detecting the occasional signal among many rapid neutral signals.

Actual sampling during the work itself was even more promising than effective threshold techniques. Recent experiments at Farnborough had shown that vigilance fell off after 40 min.—which was very close to the earlier findings[4].

A full study was now needed of the relationships between vigilant behaviour and neurophysiological measures. The chairman of the meeting (Prof. J. Drever) had developed electroencephalogram techniques which Mr. Fraser suggested should be used to detect changes in the neurophysiological pattern during vigilance tasks.

OBITUARIES

Dr. H. R. Kraybill

HENRY REIST KRAYBILL, who died in Chicago on September 30 at the age of sixty-five after several months illness, was particularly well known for his research studies on meat and meat products over the past fifteen years.

After graduating in agricultural chemistry at Pennsylvania State College in 1913, Dr. Kraybill took his doctorate at the University of Chicago in 1917. He organized and developed the Departments of Agricultural Chemistry first in the University of New Hampshire from 1919 until 1924 and then in the Purdue University from 1926 until 1941. During this period, he also served as State chemist for New Hampshire and Indiana and held appointments at the Boyce Thompson Institute and the United States Department of Agriculture.

He returned to Chicago in 1941 as director of the Department of Scientific Research of the American Meat Institute and as professorial lecturer in the

Department of Biochemistry at the University of Chicago. When the American Meat Institute Foundation was formed in 1947, it was a natural consequence that he should become its first director of research and education. In 1955 he became in addition vice-president of the research organization of the Institute. At different periods, he held office as president of the Association of Agricultural Chemists, the American Association of Feed Control Officials, and the American Society of Plant Physiologists, and as chairman of the Division of Agricultural and Food Chemistry of the American Chemical Society.

From his earlier work in the fields of plant biochemistry and physiology, Kraybill turned in 1941 to pioneer work in the chemistry of meat and meat products. One of his most important contributions in this field was the discovery and development of two antioxidants for animal fats which not only inhibited development of oxidative rancidity in the fat alone but also inhibited the development of rancidity in manufactured products containing the fat. He learned just before his death that for this work he had been chosen for the Dodge and Olcott Award for 1956.

Earlier in the year, the Purdue University had conferred on him an honorary degree of doctor of science in recognition of his service to the University and his achievements as a scientist, teacher and administrator in the science of agriculture.

Dr. Kraybill was of a quiet, retiring disposition and always gave a very warm welcome to visitors from Britain to the United States. J. G. SHARP

Prof. James M. Sherman

PROF. JAMES M. SHERMAN, professor of bacteriology in Cornell University since 1923 and head of the University's Department of Dairy Industry, died on November 5 at the age of sixty-six. He had relinquished his administrative duties as departmental head on July 1, 1955, in order to devote his full time to writing and research.

Prof. Sherman was a graduate of the North Carolina State College and the University of Wisconsin. Before going to Cornell, he held teaching posts in the University of Wisconsin and Pennsylvania State University, and he was bacteriologist in the U.S. Department of Agriculture during 1917–23. He was a past-president of the American Dairy Science Association and of the Society of American Bacteriologists.

Prof. Sherman was the author of more than a hundred research papers, and published a book on laboratory methods in bacteriology and a monograph on the streptococci. His major research work concerned general biological studies of micro-organisms, systematic studies of some of the important groups of bacteria, especially the streptococci, and investigations of the micro-organisms of importance in milk, food products, soil and industrial fermentations. He served as editor-in-chief of the *Journal of Bacteriology* (1944–51), and associate editor of the *Bacteriological Reviews* (1937–44), and at the time of his death he was a member of the editorial committee of the "Annual Review of Microbiology".

NEWS and VIEWS

Agriculture in the University of Melbourne: Sir Samuel Wadham

SIR SAMUEL WADHAM retires at the end of 1956 from the chair of agriculture in the University of Melbourne after thirty years in that position. Sir Samuel took his first degree at Cambridge (Christ's College), and after the First World War, when he served in the Middle East, he returned to Cambridge as a senior demonstrator in botany. He was invited in 1926 to go to Melbourne as the first professor in a reorganized Department of Agriculture. During his occupancy of the chair some four hundred students have taken their degrees (B.Agr.Sc.), and his graduates comprise a hundred of the scientific staff of the Victorian Department of Agriculture. His own career has been especially marked by the calls that have been made by governments on his skilled services as an adviser in the field of land utilization; in particular, he played a major part in two Commonwealth Commissions, one into the wheat, flour and bread industries during the mid-1930's, and the other the Rural Reconstruction Commission, 1943–45, which advised on policies of post-war land settlement. The chief lines of work carried out in the School under his direction and stimulus have been surveys of soil and land utilization and standards of living. His "Land Utilization in Australia", first produced in 1939 in collaboration with Prof. G. L. Wood, has become an accepted text-book, and is now in its third edition. Apart from his work for agriculture, Sir Samuel has played a major part as a university administrator and in interpreting the university to the public. Through personal visits and regular broadcasts he has become widely known and loved throughout the Australian agricultural community. His exceptional services to Australia were recognized by the award of a knighthood in the New Year Honours in 1956.

Dr. H. C. Forster

DR. H. C. FORSTER, who succeeds to the Melbourne chair of agriculture, is a graduate of the school of which he now becomes the head. His published work deals with factors determining the yield of wheat, and his degree of Ph.D. in statistics was taken at the University of Iowa during the tenure of a Commonwealth Fund Fellowship in 1935–37. He first joined the Victorian Department of Agriculture, in which he became senior cereal research officer, and for many years he has been a part-time lecturer on cereal crops in the University's School of Agriculture. He was president of the Australian Institute of Agricultural Science in 1955, and chairman of the central executive of War Agricultural Committees during the Second World War. Since 1949 he has been assistant executive officer of the Commonwealth Scientific and Industrial Research Organization. He brings to his new post an exceptionally wide knowledge of agriculture and agricultural research throughout the Commonwealth.

Awards for University Education

IN a debate in the House of Commons on November 29 on university awards, Mr. J. C. Jennings, Mr. F. Mulley and Lord Balniel pressed for the establishment of a working party to examine the possibilities of a central award-giving body, and to advise the Minister in connexion with the forthcoming triennial review of awards. Mr. B. Vosper, Parliamentary Secretary to the Ministry of Education, declined to commit himself, but agreed that the problem is due for review. He said that the Minister is considering the probable effect of the projected university expansion on awards policy, but he sees no reason why the system of awards should fail to meet the proposed expansion, and he accepts the view that our policy should be to ensure that young persons desiring and capable of receiving university education should not be deprived of it. In 1955, he pointed out, 15,900 of the 18,000 United Kingdom students entering the English and Welsh universities held Ministry or local authority awards, and of these, 12,500 held local authority awards, an increase of 25 per cent on the figures for 1951. Moreover, every local authority has now come into line so far as awards and the basis of assessment are concerned, and there has been a considerable advance towards uniformity in vacation allowances and like matters. Complete uniformity has also been secured in regard to consideration of candidates with two passes in the General Certificate Examination at the advanced level.

Scientific and Technical Co-operation in Africa

An admirable record of scientific and technical co-operation has been issued by the Commission for Technical Co-operation in Africa South of the Sahara and by the Scientific Council for Africa South of the Sahara, the secretariats of which were amalgamated on January 1, 1955, to ensure maximum co-ordination between two complementary organizations. In 1955 the Commission extended its inter-African consultations to include the social sciences and convened the first meeting of the Inter-African Conference on the Mechanization of Agriculture as well as scientific meetings on the control of quelea birds and the use of irrigation water in drainage and agriculture. Recommendations have been submitted to member governments which may lead to the adoption of a standard system of meteorological and climatological data for the African continent, while studies have continued on strictly regional problems in soil conservation, land utilization and the scientific aspects of geology. The work of the two organizations to 1955 is reviewed in a series of chapters covering pedology, agriculture and forestry; meteorology, climatology, irrigation and drainage; physical hydrology; animal resources; protection of natural resources and of agricultural production; geology; cartographic and statistical data; co-operation in the field of health; inter-African co-operation in social welfare and education; inter-African co-operation in the field of labour; joint action in the social sciences. They show that the activities of the Commission and of the Council now cover practically the whole scientific and technical field, while international contacts are also being widened. Chronological extracts from the annual reports of the Scientific Council for Africa, 1949–55, and from the technical conferences held under the ægis of the Commission, 1948–55, are also included, and there is a general index.

Life-History of the Desert Locust

"The Ruthless One", a new film on the desert locust made by the Shell Petroleum Co., Ltd., succeeds in the short screen time of 18 min. in being equally interesting to the lay viewer and to the advanced student and teacher. The life-history of the desert locust is splendidly shown in colour, with close-up sequences of mating and egg-laying, and all stages of growth from the new hatchling to the winged adult. Since no amount of patient preparation can ensure demonstration of these processes on living material, this cannot fail to be of value to teachers. The nature and size of the locust problem are illustrated briefly, and some sequences made in the Anti-Locust Research Centre in London show the work of that organization, particularly in the collection and dissemination of information. Some shots show research in the laboratory and in wind tunnels. With commendable self-effacement, the film does not deal at length with the practical achievements in field-methods of locust control. Scientists are inevitably divided in their attitude to all steps at popularization. The slightly melodramatic title is explained as a translation of *Al Garad*, one of the Arabic names given to the locust. Then the question of musical background: Can the public never absorb information without it? However, it is well-composed music and anyone who has enjoyed, say, "Peter and the Wolf", will enjoy the background to the courtship scene. Issued in conjunction with the film is an illustrated booklet, 'The Hungry Thief"; this will help the layman—and perhaps the administrator—to understand the recent progress made in the locust problem.

A New Reactor Course at Harwell

New opportunities for industry to acquire basic knowledge of nuclear energy are offered by a special course which has been arranged at the Harwell Reactor School. The standard Reactor School course is one of fourteen weeks duration, giving instruction primarily in reactor physics and engineering. Present arrangements enable some students to attend only the first six weeks of this course, during which time the basic principles of these subjects are taught; but the numbers of these students have had to be limited because the demand for places on the standard course has been high.

During June 3–July 12, 1957, a special six weeks course is to be run entirely separately, and some sixty places will be available. Besides covering the basic principles of the physics and engineering of reactors, lectures will be given on such subjects as reactor metallurgy, shielding and health physics. In addition, emphasis will be placed on special topics such as the instrumentation of reactors and the use of radioisotopes in industry. This special course is designed primarily for people of degree standard who are not directly concerned with overall reactor design. It should appeal especially to members of firms whose interest lies in the making of ancillary equipment for reactors. Application forms can be obtained from the Reactor School, Atomic Energy Research Establishment, Harwell, Berkshire.

Conference of Farm Historians

Sir James Scott Watson took the chair at the winter conference of the British Agricultural History Society held in December in co-operation with the Association of Agriculture at the Institute of Education, University of London. The conference listened to three papers: one by Mr. F. C. Payne, of the Welsh Folk Museum, St. Fagans, on "The Plough in Britain", and a second by Miss E. M. Marston, lecturer in horticulture at the University of Nottingham, on

"The History of Plant Propagation in England". The third was by Mr. G. E. Fussell, on "The Grasses and Grassland Cultivation, 1500–1900".

All three papers were devoted to some aspect of the history of farming technique, and this is in accordance with the policy of the Society. At the annual conference normally held at the end of April, papers on local history or on some aspect of economic or social history are presented. If local, the lecturers usually try to deal with the neighbourhood in which the conference is held. At the winter conference in December, papers on technical history are read. Papers read at the conferences are not necessarily printed in the *Agricultural History Review*, which is published by the Society and distributed free to members. It appears twice a year and includes notes, original papers and book reviews. It can also be purchased by non-members. The honorary secretary, Mr. J. W. Y. Higgs, Museum of English Rural Life, 7 Shinfield Road, Reading, will welcome inquiries from anyone interested.

Toxic Hazards of Pesticides to Man

THE development of strains of insects which are resistant to the usual pesticides may make it necessary to change over to the use of more dangerous substances, for example, in the control of malaria. This is one reason why it is important that the study of the toxicity of modern pesticides and of the precautions necessary in handling them should be actively pursued. A study group set up by the World Health Organization under the chairmanship of Dr. J. M. Barnes (Serum Research Institute, Carshalton, Surrey) has just summarized its findings (World Health Organization: Technical Report Series 1956, No. 114; pp. 51. H.M.S.O; 3*s.* 6*d.*). The report contains useful information on the pesticides containing chlorine and phosphorus and on their toxicity to man and the higher animals, and makes suggestions for safeguards in their use, both indoors and outdoors. Further lines of investigation are suggested. Blood cholinesterase estimation is the most reliable test of harmful exposure to the organo-phosphorus insecticides, such as parathion. An appendix gives the names of the institutions and their individual workers in the different countries where problems of insecticide toxicity towards vertebrates are being studied. Information is included on the compounds being investigated and the general types of work being done in the different centres.

Amino-acid Metabolism in Detached Leaves

C. D. Nelson and G. Krotkov (*Canad. J. Bot.*, 34, 4, 423; 1956) have investigated the metabolism of carbon-14 amino-acids and amides in detached leaves of the broad bean. Leaves were placed with their petioles in 0·01 *M* ammonium nitrate and allowed to carry on photosynthesis in carbon-14 dioxide for various periods from 12 to 125 min. The radio-activities of the various amino-acids were degraded by decarboxylation with ninhydrin. From the specific activity data it was concluded that the amino-acid closest to the site of carbon dioxide fixation in photosynthesis was alanine, followed by aspartic and glutamic acids, with the amides farthest removed. From the intramolecular distribution of label it was concluded that asparagine and glutamine were formed from their corresponding amino-acids. The labelling in aspartic and glutamic acids was not consistent with the view that these two amino-acids are formed from their corresponding α-keto acids produced by operation of the conventional tricarboxylic acid cycle. A C_2 plus C_2 condensation is postulated for the formation of aspartic acid. A shift in the double bond in the aconitase reaction of the tricarboxylic acid cycle would account for the observed labelling in glutamic acid. When acetate-1-carbon-14 was fed to detached broad bean leaves in the light or dark, the distribution of label in glutamic acid supported the suggestion that there is such a shift in the double bond in the aconitase reaction. Sodium arsenite, infiltrated into tobacco leaves, inhibited the biosynthesis of asparagine but not that of glutamine.

Proceedings of the Fifth Colloquium Ampère

THE texts of the twenty-four contributions to the Fifth Colloquium Ampère, held in Geneva during March 21–23, are printed in a special number of Vol. 9 of the *Archives des Sciences*. Nine different countries are represented. Most of the contributions are brief, being only one or two pages in length, and the main topics of discussion are the properties of dielectrics at high frequencies, ferrites, and paramagnetic and nuclear resonance. Review articles are contributed by C. J. Gorter (Kamerlingh Onnes Laboratory, Leyden) on investigations on magnetic resonances during the past twenty years in the Netherlands; L. Guilotto (University of Pavia) on recent work on the time of nuclear relaxation performed at Pavia; A. Losche (Physikalische Institut, Leipzig) on work on paramagnetic nuclear resonance at Leipzig; P. Grivet (University of Paris) on the development of nuclear resonance in France and on recent progress in experimental methods in the United States; and C. H. Townes (École Normale Supérieure, Paris) on recent developments regarding the measurement of time. The contributions are all in French, and no abstracts are provided.

Functions of the Natural History Museum

SIR GAVIN DE BEER, director of the British Museum (Natural History), has served a useful purpose by preparing some observations on the functions of natural history museums in general and of the Natural History Museum in particular. It was appropriate that it should appear during "Museums Week" (October 7–13), which was sponsored by the International Council of Museums. Sir Gavin describes the purpose and object of natural history museums and then details their educational function. Stress is laid on the importance of scientific research in natural history museums and the claim is justly made that they are indispensable instruments of modern civilization and human welfare. Apparently this exceedingly useful paper is not a publication in the usual sense of the term, but no doubt copies can be obtained from the British Museum (Natural History) by those interested.

Textile Institute Award for Technical Teachers

THE Textile Institute has decided to make a special award of a medal and £20, which, by arrangement with the City and Guilds of London Institute, is offered in that organization's Technical Teachers' Certificate examination to the most successful candidate who is a part-time teacher of textiles. The first recipient is Mr. Robert Noel Ward, of Liverpool, a research chemist with British Enka, Ltd., and part-time lecturer in the manufacture of rayon and plastics at Mount Street Institute of Further Education, Liverpool.

University of Glasgow

THE following appointments have been made in the University of Glasgow. To the newly created Simson chair of mathematics: Ian M. Sneddon (see *Nature*, 177, 1109; 1956). To senior lectureships: D. R. Bowes (geology) and W. R. Rees (agricultural chemistry, in succession to F. E. Moon). To lectureships: P. V. March and Helmut Mykura (experimental physics), R. H. Pritchard (genetics), D. R. Powell and D. S. Weedon (geology) and J. S. Gillespie (physiology). To Imperial Chemical Industries Fellowships: R. N. Thomson (biochemistry), A. I. Scott and G. A. Sim (chemistry), and R. E. Azuma (physics). To a Nuffield Fellowship in chemistry: C. R. Narayanan. To a Fellowship in natural philosophy: R. V. Hesketh.

Prof. D. H. R. Barton has been granted leave of absence to visit the United States during April 1957, to receive the Fritzsche Medal of the American Chemical Society. For the present session, 412 new students (290 men and 122 women) have been admitted to the science departments, compared with 343 in 1955. In the University as a whole, the total number of matriculated students has increased by about 200 to 5,910.

Oversea Service Division: Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: P. Adams (principal agricultural officer, Sierra Leone), assistant director of agriculture, Western Nigeria; D. A. Donald (senior agricultural officer, British Solomon Islands Protectorate), principal agricultural officer, Northern Nigeria; J. W. D. Goodban (director of agriculture, British Honduras), director of agriculture, Sierra Leone; G. B. Gregory (agricultural officer, Fiji), senior agricultural officer, Fiji; K. Landskrower (agricultural officer, Gold Coast), senior agricultural officer, Gold Coast; G. E. O. Okiy (agricultural officer, Eastern Nigeria), principal, School of Agriculture, Eastern Nigeria; W. V. Rose (deputy director of agriculture, Barbados), assistant director of agriculture, Western Nigeria; M. J. Smith (agricultural officer, Federation of Malaya), agricultural officer, North Borneo; E. C. Clarke (assistant conservator of forests, British Guiana), assistant conservator of forests (class 2), Cyprus; T. W. Hussey (senior assistant conservator of forests, Federation of Nigeria), conservator of forests, Southern Cameroons, Federation of Nigeria; P. B. H. Bailey, D. Bleackley and P. H. A. Martin Kaye (geologists, Geological Survey Department, British Guiana), senior geologists, Geological Survey Department, British Guiana; C. G. Dixon (senior geologist, Geological Survey Department, British Guiana), deputy director of geological surveys, Geological Survey Department, British Guiana; J. F. Archibald (senior scientific officer, Uganda), principal scientific officer, Uganda; J. T. Davey (entomologist, Department of Agriculture, Federation of Nigeria), senior scientific officer for posting to the Organisation Internationale contre le Crequet Megratem, Africa; A. L. Wharton (scientific officer, West African Cocoa Research Institute), senior scientific officer, West African Cocoa Research Institute; W. Wilkinson (scientific officer, Commonwealth Institute of Entomology), scientific officer, West African Termite Research Unit; J. F. Hart (provincial veterinary officer, Kenya), assistant director (field services), Veterinary Department, Kenya; R. W. E. Lewis (provincial veterinary officer, Kenya), assistant director (field services), Veterinary Department, Kenya.

Announcements

AT the annual general meeting of the Photoelectric Spectrometry Group the following officers were elected: *Chairman*, Dr. E. M. F. Roe (Chester Beatty Research Institute); *Vice-Chairman*, Mr. J. R. Stansfield (Hilger and Watts). Mr. R. A. Ford (British Nylon Spinners, Ltd.) and Mr. A. W. S. Tarrant (National Physical Laboratory) were elected to the two vacancies on the committee of the Group.

THE Fifth International Low-Temperature Conference on Physics and Chemistry will be held at the University of Wisconsin, Madison, Wisconsin, during August 25–31. Further details will be issued in due course.

AN International Congress on prestressed concrete will be held in Berlin during May 5–10, 1958. Contributions, which should not exceed 4,000 words, must be in one of the four languages, English, French, German or Spanish, and must contain a brief summary in all four languages. Six copies are required and should be received by the general secretary of the Fédération Internationale de la Précontrainte, Mr. P. Gooding, c/o Cement and Concrete Association, Terminal House, 52 Grosvenor Gardens, London, S.W.1, not later than August 1, 1957.

AN International Symposium on "Purity Control by Thermal Analysis" will be held in Amsterdam during April 24–26, 1957, under the auspices of the International Union of Pure and Applied Chemistry and the Commission on Physicochemical Data and Standards. Papers covering all aspects of the subject will be presented by recognized specialists from several European countries and from the United States. Those wishing to attend should apply to the secretary, Dr. W. M. Smit, Centraal Instituut voor physische-chemische Constanten, Biltstraat 172, Utrecht, Holland, for a form of application for membership. Those who register before December 31, 1956, will receive a set of preprints of the papers.

THE Worshipful Company of Glass Sellers of London is offering up to four scholarships in glass technology, tenable at the University of Sheffield. In suitable circumstances, these qualify for supplementation by the Ministry of Education up to the full value of State Scholarships. Further information can be obtained from the Registrar, University of Sheffield, Sheffield 10.

APPLICATIONS are invited for the Helen Putnam Fellowship for Advanced Research, a postdoctoral resident fellowship for women, with research facilities at Harvard University. The research may be in any field related to genetics or mental health, including psychology, child development and other fields of social science. The stipend will be 3,000 dollars a year, with possibility of renewal. Application forms may be obtained from the Secretary, Graduate School, Radcliffe College, Cambridge 38, Massachusetts, U.S.A. Completed applications should be returned not later than January 15, 1957. Announcement of award will be made on or before February 15, 1957.

MAGNETIC RESONANCE

SYMPOSIUM AT BANGOR

A SYMPOSIUM on "Magnetic Resonance" was held at the University College of North Wales, Bangor, during September 26–27, the meeting being sponsored by the Liverpool and North Wales Branch of the Institute of Physics. A hundred and twenty persons attended, of whom twelve came from overseas. The growing appreciation in Britain of the value of nuclear and electron magnetic resonance as analytical and structural tools was revealed by the presence of many chemists and physicists from industry.

The meeting opened with a lecture by Mr. R. Kamper (Clarendon Laboratory, Oxford), who gave an account of resonance experiments on free atoms, in which resonance is detected by enclosing the atoms in a resonant microwave cavity, and measuring the absorption of power as a function of the applied magnetic field. In this way the structure of the magnetic energy-levels is explored, yielding the same kind of information as that provided by atomic beam resonance experiments, but without the attendant difficulties of detection. He went on to describe some current work of Dr. Bleaney's group at Oxford on two isotopes of iodine, free atoms of which are obtained by photo-dissociation of the molecular gas within the cavity itself. This method should be applicable to a large number of atoms and free radicals.

Dr. J. G. Powles (Queen Mary College, London) explained with the aid of a film the formation of spin echoes in nuclear magnetic resonance. The nuclear magnetic moments in a specimen which is usually liquid are first aligned by a steady magnetic field. A pulse of radio-frequency power is then applied which tips the aligned moments through an angle so that they now precess freely about the direction of the steady field with their Larmor frequencies. Since the steady field is never quite uniform, the Larmor frequency is different for different parts of the specimen; the individual moments, therefore, soon get out of phase with each other. At a time τ, a second radio-frequency pulse is applied which turns the nuclear moments round; they now pick up their phase differences at the same rate that previously they had lost them, and come into phase coherence again at a time 2τ. In this temporary condition of recovered phase coherence, the nuclear moments induce a signal in a coil wound around the specimen; this signal is the spin echo. By studying the size of these echoes and of other echoes formed by additional pulses, the two relaxation times T_1 and T_2 can be measured. If a nucleus diffuses from one part of the liquid specimen to another part where the steady field is different, its Larmor frequency changes, and it no longer recovers its original phase at time 2τ and is unable to contribute to the echo. A study of the reduction of echo amplitude due to this cause gives information about the rate of diffusion of molecules in liquids. The latent phase 'memory' in the specimen between the initial pulse and the echo can be used as an information storage device for digital computers.

Mr. G. S. Waters (Signals Research and Development Establishment, Christchurch) explained how the free precession of nuclear moments in a steady magnetic field provides a method for accurately measuring the Earth's field. The protons in a vessel of water are aligned in a field of about two hundred gauss produced by passing current through a coil wound around the vessel. When this field is suddenly switched off, the protons precess in the very uniform field of the earth and induce a signal at their precessional frequency (roughly two kilocycles) in the coil wound on the vessel. By accurately measuring this frequency, the Earth's field-strength can be measured absolutely to about one part in 40,000; relative values at different times of day or in different places can be obtained with even higher accuracy. Mr. Waters and his colleagues demonstrated to the conference a nuclear free precession magnetometer which they had built.

Prof. E. R. Andrew (University College of North Wales, Bangor) reviewed current work in physics at Bangor. He reported measurements of the quadrupole-split spectrum of sodium nitrate, and the verification of first- and second-order theory. The second moment of the centre line has been measured and is in fair agreement with recent theoretical predictions. The relaxation mechanism in this crystal is being studied and a new method was described for determining whether the mechanism is magnetic or quadrupole in origin. When applied to sodium nitrate, the mechanism is found to be quadrupolar. The results were reported of a calculation of the spectrum expected from triangular groups of protons slightly distorted from equilateral form. It was shown that in certain acid hydrates the oxonium ion must be very nearly equilateral in form, the possible departure consistent with experiment being not more than about ten per cent. The traditional X-ray work on metals and alloys is being maintained in the department. Work was reported on a range of alloys similar to the ferromagnetic Heusler alloys, but with silver or gold replacing copper, and also on binary alloys of manganese with silver and gold; the structure and magnetic susceptibility have been measured over a wide range of temperature. A critical temperature of 190° C. for the order–disorder transformation in $CuAu_3$ has been found by X-ray and resistivity measurements. An increase in resistivity of disordered Cu_3Au near the critical temperature, found by pulse-anneal measurements, is attributed to short-range order. Work on nickel–zinc ferrites has shown that the resistivity obeys the simple exponential dependence on temperature characteristic of semiconductors, with no discontinuity at the ferrimagnetic transformation temperature. On the other hand, the magneto-resistance is closely associated with the ferrimagnetism.

All magnetic resonance work requires a magnetic field, and the provision of a suitable magnet is usually the most difficult problem confronting the experimenter. Dr. R. E. Richards (Physical Chemistry Department, Oxford) summarized the desirable attributes of magnets for electron magnetic resonance and for low- and high-resolution nuclear magnetic resonance. Uniformity of magnetic field to 1 part in 10^5 over a volume of 1 cm.^{3}, coupled with a stability rather better than this, generally suffices for electron work and for low-resolution nuclear work, and can be provided at modest cost by permanent magnets or electromagnets. On the other hand, high-resolution nuclear magnetic resonance spectroscopy demands a uniformity of one part in 10^7 and stability to better than this. A large carefully engineered electromagnet with first-class electronic regulation will meet the requirements, and indeed such a magnet is marketed in the United States. A large carefully engineered permanent magnet with temperature stabilization is equally satisfactory. In either case the cost is high. Dr. Richards outlined Purcell's method of smoothing out irregularities of field caused by inhomogeneity of the magnet alloy; the pole caps are made of layers of soft iron and diamagnetic material which attenuate the irregularities in much the same manner that electrical fluctuations are reduced by the successive sections of a filter. In the discussion which followed, diverse views were expressed on most aspects of design—pole-cap contour and figuring, shims, pole-cap material, magnetic material, yoke configuration. It seems that much has yet to be learnt before one can confidently assert what are the best and most economical designs of magnets suitable for high-resolution work.

At a business session held during the symposium, a proposal was approved to form a Radiofrequency Spectroscopy Group which would arrange future occasional meetings. For this purpose radiofrequency spectroscopy was deemed to cover work at all frequencies up to about 10^{11} c./s., and therefore includes electron- and nuclear-resonances and also microwave spectroscopy of gases.

E. R. ANDREW

ANNUAL CONFERENCE OF THE PHILOSOPHY OF SCIENCE GROUP

THE first annual conference of the Philosophy of Science Group of the British Society for the History of Science was held during September 21–23 at Ashburne Hall, University of Manchester, under the chairmanship of Dr. G. J. Whitrow, chairman of the Group, and was attended by about fifty members and guests. Mr. R. F. J. Withers acted as conference secretary.

Symposia were held on "Cybernetic Models and Thought Processes", "The Nature and Scope of Scientific Method", "The Status of Irreversible Processes in Physical Theory" and "The Role of Historical Explanations in Science".

In the first symposium, papers were read by Dr. W. Mays and Dr. W. Ross Ashby, and Prof. J. H. Woodger took the chair. Dr. Mays raised the question of the adequacy of cybernetic models for human thinking and learning behaviour. He held that the question, 'Can machines think ?' is not simply a semantic but a factual one; and the answer is 'Yes' only if machines and humans reach their conclusions by similar processes. Dr. Ashby was interested in giving a clear account of 'model' as something that is from a relevant point of view similar to that which is modelled, so as to lead to results which can be tested. To be tractable, however, a model must also be an over-simplification. Hence, all models of the brain have been inadequate, but they have thrown light on aspects of it; in particular they have focused attention on the basic question, 'How much information is involved in this process ?' Subsequent discussion centred around the concept of model, its nature and role. There seemed to be a general consensus of opinion that, although mental processes have not so far been adequately represented by cybernetic models, some models have proved useful.

A connecting link developed between this discussion and the next one, for in discussing models attention was directed to the role of theories in science. This question figured prominently in the second symposium. For this the chair was taken by Dr. J. O. Wisdom, and the opening paper was given by Dr. G. W. Scott Blair on "Scientific Method as a Specialized Intellectual Activity". He considered that the mental processes involved in scientific activity consist of observing, selecting, relating and deducing. He pointed out that there are parallel processes involved in tests of general intelligence, and therefore claimed that the specialized mental activity that goes to make science is not unique but is shared by other intellectual activities. Prof. R. O. Kapp followed with a paper on "What is a Law in Physics ?" He laid great stress on what he called the principle of minimum assumption. He showed with examples that this is not merely a method of economy but also provides a means of deriving important results in theoretical science. He considered, for example, that Dirac could not have predicted the positron without (though perhaps not overtly) relying on this principle. Mr. Z. M. T. Tarkowski then spoke on "The Interaction of Experiment and Theory in Science". After giving an account of the general way in which theories are used, he contended that Galileo's experimental results did not bear out his kinematical hypotheses, and inferred that a theory may have the right to be regarded as possibly true even though the evidence is against it.

The third symposium was more specialized. The chairman of the Group took the chair, and Prof. M. S. Bartlett read a paper on "Irreversibility and Statistical Theory", in which he presented a survey of the development up to the present day of the concepts of irreversibility and entropy. He pointed out that the paradoxes of reversibility reappear in statistical mechanics. He suggested that statistical reversibility for very small systems is consistent with their possible lack of any intrinsic time-direction. Mr. L. L. Whyte then spoke on "The Mathematics of One-way Processes", the traditional problem being to account for one-way processes moving towards equilibrium on the assumption that elementary atomic processes are reversible. This he regarded as over-simplified, since owing to the effect of magnetic fields no single electronic process is reversible unless all electronic motions are simultaneously reversed. A more fertile problem may be to determine conditions under which certain constant parameters can provide satisfactory approximations in a theory of one-way processes. In the discussion which followed, a short note was presented by the chairman from Prof. K. R. Popper, who argued that no logically satisfactory version of the second law of thermodynamics exists. He suggested a possible reformulation of the law, but directed attention to the serious logical difficulties in the way of any reformulation.

In the final symposium, Mr. R. P. Gould discussed "The Place of Historical Propositions in Biology". He contrasted explanation in science with explanation in history. After describing similarities and differences between the kinds of statement found in science and history, he aimed at showing how scientific explanatory hypotheses can be used to explain what has happened in the past. In this way it is possible to give scientific explanations about the evolution of extinct organisms; but he considered that, because of inadequate information, statements about the physiology, biochemistry, and so on of extinct organisms must be treated with caution. Mr. J. W. N. Watkins then spoke on "Historical Explanations in the Social Sciences". He advocated 'methodological individualism' as an essential principle for social science. According to this principle, there are no 'holistic' sociological laws that are irreducible to laws about the situations, dispositions, aims, etc., of individual persons. He claimed that the principle could account for organic-like social behaviour, and he described ways in which explanations of social regularities and of unique historical events could be framed in accordance with it. Mr. R. F. J. Withers, who took the chair, pointed out that there is a difference between scientific explanation and the use of techniques; and the general discussion showed that several biologists were loath to look on scientific explanation, when applied to evolution, as historical.

Animated discussions took place in each symposium. The conference was generally felt to have justified the efforts of those responsible for organizing it, particularly as it became evident that greater clarity concerning problems of scientific method and explanation could facilitate further progress in science itself. Plans for future conferences outside London were discussed. It was provisionally arranged that the next will be held at a week-end towards the end of September 1957. An announcement will be made in *The British Journal for the Philosophy of Science* early in 1957.

NUFFIELD FOUNDATION

REPORT FOR 1955–56

THE eleventh report of the Nuffield Foundation, covering 1955–56*, specially emphasizes in its introduction the general ideas on which the Foundation attempts to plan its operations. Concerned to finance projects that may yield dividends not in terms of cash but of public good, the Foundation inquires first into the credit-worthiness of the applicant; second, into the originality of his idea; and third, into the soundness of his project. It is least interested in investments which will produce a modest return, and with depressing frequency it may find that the number of good projects exceeds the number of good men to execute them. Moreover, the Foundation must also go out and seek profitable investment. It is not its job to sustain work which everybody agrees ought to be done; it dare not even continue to support indefinitely its own successful schemes, lest it quickly consume resources out of which new ones can be attempted. In this seeking of new and rewarding ventures, the Foundation is greatly helped by its visitors and advisers, including those from the universities, learned societies, research institutes, philanthropic societies, hospitals and government departments, who bring ideas as well as information. The Foundation must be free to make rapid changes of emphasis in its interests, and it is important that the size of a grant should be nicely judged so as not to stunt nor stifle. Its funds, too, should not be scattered over a wide range of unrelated schemes, and its policy should be neither vague nor rigid, its programme neither shapeless nor fixed.

Grants for biological research in the United Kingdom include a further grant of £2,410 for one year to The Queen's University of Belfast for studies on population genetics in Northern Ireland under Prof. A. C. Stevenson which are gradually building up a detailed knowledge of the frequency and distribution of specific genes. A grant of £4,800 over five years has been offered to the Plant Breeding Institute, Cambridge, for the salary of a plant cytologist with some knowledge of biochemistry to work mainly at the Institute under the joint supervision of its director, Dr. G. D. H. Bell, and of Prof. J. S. Mitchell, of the Department of Radiotherapeutics, on the modification by chemical means of radiation effects in plants such as broad beans and barley. A further grant of £4,500 over 1956–59 has been made to the University of Glasgow for the work under Prof. G. Pontecorvo on the genetics of micro-organisms, which it is hoped may lead to the discovery of a chemical basis for the genetical phenomena of 'crossing over'. A further grant of £14,200, payable in declining amounts over five years to the Royal Anthropological Institute, London, is to enable the Nuffield Blood-Group Centre to continue its work until other financial provision can be made, and the grant to the Lister Institute of Preventive Medicine, London, for the work on the chemical analysis of immunity-provoking agents has been renewed at the rate of £3,000 a year for a further five years.

A grant of £4,850 over three years has been made to the University of Oxford in support of Dr. A. E. M. Weddell's study of free nerve terminals in the cornea of untreated leprotic patients, and an additional grant of £12,000 over three years has been made to University College, London, for work on the problems of analogues for the cerebral mechanisms involved in the learning processes of the octopus; £6,300 over three years to the Institute of Psychiatry, University of London, is for Prof. H. McIlwain's work on the control of metabolism in normal mammalian cerebral tissues. Another grant to University College, London, of £4,246 over three years, is for the construction of a micromanipulator which will transmit the sense of touch. The Foundation has provided £2,500 for the Department of Agricultural Botany, University College of Wales, Aberystwyth, for equipment to control light, temperature and humidity in research on the influence of environment on the mechanics of growth and inheritance. A final grant of £2,700 over three years has been made to the University of Cambridge for Dr. J. W. Millen's and Dr. D. H. M. Woollam's work on hydrocephalus in rabbits due to deficiency of vitamin A, and a grant of £2,530 has been offered for work on the flight muscles of the bumble bee and on the electric discharges from fishes. The Foundation has also offered £1,500 a year for a further two years to the University of Durham in support of Prof. J. Baddiley's work on the structure and synthesis of co-enzyme *A*.

Other scientific grants include £1,750 a year for two years for the establishment of a lectureship in polar studies at the University of Durham; £8,000 over four years to the Imperial College of Science and Technology, London, for Prof. R. M. Barrer's work on the synthesis and properties of natural and synthetic minerals, especially aluminosilicates; £600 for special equipment and £1,200 over three years for a research assistant for work in the Department of Physics, University of Cambridge, on the use of X-ray diffraction methods to measure electron density distribution in chemical bonds; and a further £880 to the University of Cambridge for Dr. D. J. Price's work on the history of scientific instruments. The Division for Architectural Studies of the Nuffield Foundation has now taken up a study of tropical architecture in relation to human comfort and has been invited to design halls of residence and a dining hall for students of the Imperial College of Tropical Agriculture, Trinidad. Its survey of requirements in laboratories in England and Scotland was to be completed in mid-September, 1956, and its study of the environment to be provided for children in hospital has led to the delineation of a series of problems needing special study, while at Musgrove Park Hospital, Belfast, the Division's experimental work has brought down the cost of efficient and attractive accommodation to about £1,000 a bed.

---

* The Nuffield Foundation. Report for the Year ended 31 March, 1956. (Eleventh Report.) Pp. 160. (London: Nuffield Foundation, 1956.)

Apart from chronic rheumatic diseases, to which the Foundation devotes the income of the Oliver Bird Fund and a like amount from its other resources, the Foundation does not normally assist the study or treatment of specific diseases. In this field the Foundation's financial help during the present period goes mainly to the Rheumatism Research Centre in the University of Manchester and to the Rheumatic Unit at the Northern General Hospital, Edinburgh. Besides additional grants of £70,000 over eight years and £65,750 over five years a new grant of £10,000 over three years was made during the year to the Department of Chemical Pathology, St. Mary's Hospital Medical School, London, for further fundamental work under Dr. A. Neuberger on the tissues of the body which are involved or damaged in the rheumatic diseases. Other grants during the year for medical research include £3,000 to the Royal National Throat, Nose and Ear Hospital, London, in support of a pilot course of one year to discover the best kind of training and the best form of preliminary education of a new type of worker who will be primarily concerned with training the pre-school deaf child; £2,000 to the University of Oxford to re-equip Dr. Peter Daniel's general work, with £1,000 for equipment and £3,840 over two years for a special study, on the after-effects of tuberculous meningitis; £20,000 over five years to the University of London for the maintenance of the biomechanical unit established by the Institute of Orthopaedics and King's College to apply the methods of mechanics to the study of forces and actions in the living body; £10,000 to finance the production of a further six Melrose heart–lung machines; and £3,000 a year for two years to the Department of Surgery, University of Bristol, for work on congenital heart disease, involving the establishment of a fully documented register of cases and experimental work to correct congenital abnormalities of the heart while circulation is maintained by a pump.

In social research and experiment the largest grant during the year was £200,000 over six years to Nuffield College, Oxford, to complete the building, which is expected to be substantially finished in three years time, when the College will become residential. The group which the Foundation sent to North America in June and July 1955, to report on the agricultural advisory services in the United States, issued its report last June. The team noted that, in proportion to the value of agricultural output, the United States spends half as much again as Britain on advisory services; it was impressed by the American system of co-ordinating agricultural teaching, research and advice by basing all three on the State land-grant college; by the co-operative arrangement whereby the advisory service is jointly financed by Federal, State and County governments; and by the system of planning the year's programme in consultation with the farmers of the community, and of measuring results against defined goals. The report suggested that, if it were impracticable for university departments of agriculture in England and Wales to take responsibility for the advisory service, a strong working liaison should be established between the advisory service and university departments, agricultural colleges, and farm institutes.

Two further grants have been made to the Department of Social Anthropology of the University of Edinburgh: one of £1,500 over two years for a study of racial problems in Brixton, which appears to be an unofficial reception area for working-class immigrants from the West Indies; and £750 for a general survey of recent research into racial problems in Britain. A grant of £2,500 over two years was for Prof. C. A. Mace's investigation at Birkbeck College, London, into the aspirations of school-leavers, and £9,000 over three years has been offered to Political and Economic Planning for a study of family needs and the social services. A further grant of £5,000 was made to the Administrative Staff College, Henley, for a study of the machinery through which the relations between industry and government are conducted and an investigation into the characteristic pattern of enterprises in Britain and ways in which general policy is made, especially under the impact of change; and £1,700 a year for three years has been offered to the Department of Economics and Commerce of the University of Leeds to enable its unit for industrial management to benefit from a visiting professor or comparable expert from the United States or Canada.

A grant of £1,500 a year for two years to the University College of Swansea is for sustaining its social welfare service for overseas students to the end of the university quinquennium.

Grants for education include £3,000 to the Royal Institution, London, for its work in overcoming the shortage of science teachers; £10,000 to enable a Nuffield collection of children's books to be added to the library of children's books of the National Library for the Blind, and up to £50,000 to the Police College Trust to build and equip a dining-hall at its new premises at Bramshill House, near Hartley Witney. Grants amounting to £60,000 over three years have been offered to voluntary bodies providing chiropody for the old at reduced rates; the grant in support of Dr. D. A. Hill's gerontological research fellowship and unit, which has extended its studies to include collagen, has been renewed at the rate of £6,000 a year; besides a further grant of £2,610 over three years for Mr. F. Le Gros Clark's studies on the employment of older workers, a grant of £2,000 over two years has been made to the Slough Industrial Health Service for a study, under Mr. Le Gros Clark's supervision, to assess the possibilities of employment open to the older worker no longer able to carry on with his normal work.

Grants for the British Commonwealth overseas include £2,080 over two years to the University of Melbourne for research on the enzymes of the endocrine glands, and £1,600 for two years for Dr. V. D. Hopper's study there of heavy primary cosmic-ray particles with nuclear emulsions; £1,600 for one year for Dr. S. S. Angyal's study, with carbon-14 labelled inositol, of biochemical applications which would illuminate the role of inositol in living organisms; £18,000 towards the capital cost of a primary health unit being built by the Christian Medical College and Hospital at Vellore, affiliated to the University of Madras, to provide comprehensive care for a rural community of thirty thousand people; £3,150 during 1955–57 to the Bernard Price Institute of Geophysical Research, University of the Witwatersrand, for its study of the age of the granite of the Bushveld Igneous Complex; £7,000 for wider family studies in Jamaica; and £3,000 for capital expenditure and £2,500 for the maintenance costs over three years of an experimental farm attached to the Gayaza Girls' High School, Uganda, where progressive agriculture will be practised and taught in conjunction with dietetics.

Travel grants include £1,500 to enable Prof. E. B. Verney, of the Department of Pharmacology, University of Cambridge, to spend four months in Melbourne in research on surgical technique and another to bring to Britain for a year's postgraduate experience, Dr. Ijaz-ul-Haque, of the De Montmorency College of Dentistry, Lahore. In Britain one award was made in medicine, six in dentistry and two in biology; three fellowships were given to Home Civil servants. The scheme of travelling scholarships and bursaries for United Kingdom farmers has now come to an end, but eight scholarships were awarded during the year and four bursaries. The Foundation is now offering for a limited period each year one or two travelling fellowships to enable selected builders, building scientists or architects to study abroad at a recognized institute or with an organization of international standing. Twenty awards were made in 1955 under the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme, and the Foundation will continue its contribution of £3,000 for a further three years. On the recommendation of the Foundation's advisory committees in the Commonwealth, eleven fellowships were given in medicine, eight in natural science, four in social science and humanities, and one in engineering.

THE FLORAL MERISTEM AS A REACTION SYSTEM*

By Prof. C. W. WARDLAW

Department of Cryptogamic Botany, University of Manchester

FLORAL ontogenesis has long been a preoccupation of morphologists. In trying to understand the physiological mechanism that underlies and determines the orderly formation of the several kinds of floral organs, it is essential to consider the organization and functional activities of the apex of the antecedent leafy shoot. The most general characteristic of the growing shoot apical meristem is that it gives rise to a succession of regularly spaced leaf primordia, sometimes of very variable form and structure, these having their inception in loci of special metabolism, or growth centres. The latter typically originate in the subdistal region of the meristem. The initial state of this region, which consists of equivalent embryonic cells, may be such that the reacting metabolic substances are homogeneously distributed in it. A contemporary chemical theory of morphogenesis envisages the possibility that a reaction system of this kind, in obedience to the laws of physical chemistry and mathematics, and on being activated, can give rise to a patternized distribution of metabolites, for example, of growth centres, this constituting the chemical basis for the ensuing morphogenetic developments. This general property of the apex is maintained throughout the floral development, however much it may be modified in other ways. It is also known that the positions of new primordia are affected by those already present around the meristem.

At a certain stage in the development of a flowering plant, and often in direct relation to exposure to some characteristic photoperiod, it is held that new metabolic substances enter the apical reaction system. This substance (or substances) has not yet been specified or isolated, but it may be hormonal or enzymic in nature or action. Important, usually irreversible, changes ensue. The allometric growth pattern of the apex is radically changed; in particular, the elongation of the axis is greatly curtailed, so that the growth centres, and the lateral organs to which they give rise, are now formed in closely associated groups, either whorls or condensed helices, on an abbreviated floral axis. A characteristic feature of floral ontogenesis is that the apical reaction system passes through a sequence of well-defined phases. Physiological correlations are almost certainly involved in the changing phases of floral development, just as they are in the antecedent vegetative developments. As a result of the initial change in the state of the reaction system, the action of specific genes, hitherto inert, is induced. The changes thereby effected in the system lead to further specific genic action; and so on, until flower formation terminates with the utilization of all of the residual distal meristem. It is probably to the action of particular genes (or groups of genes), as components of the reaction system, that the clear delimitation of the several organogenic phases, that is, the formation of calyx, corolla, androecium and gynoecium, should be attributed. These several conceptions appear to afford a basis for the conspicuous features of floral ontogenesis, namely: (1) that the several floral organs are homologous with leaves; (2) that they are formed in a characteristic pattern on the meristem; (3) that the successive groups of growth centres, formed during the course of floral ontogenesis, have each distinctive physiological properties and accordingly give rise to organs which differ in form and structure from each other.

Among the advantages of the theory as outlined above are: (*a*) that it attempts to bring the morphological facts of floral ontogenesis into direct relation with physiology, genetics and the dynamic geometry of the embryonic apical region; (*b*) that many of the former highly controversial issues, for example, of homologous and non-homologous floral organs, of organs *sui generis*, of morphological 'transitions', etc., disappear as consideration of the relevant phenomena is transferred from the morphological to the physiological plane; and (*c*) that it suggests important opportunities for new observational and experimental work on floral ontogenesis, both in its more general as well as its more specific aspects. Recent investigations of the relation between metabolic factors and heteroblastic leaf development support the theory now advanced.

---

* Abstract of a paper read before the Royal Society of Edinburgh on November 5.

THE BALD EAGLE OF NORTH AMERICA

ATTACHED to the bald eagle is a degree of popular interest far beyond that normally associated with other birds of prey. Early in the history of the United States the bald eagle, of all the varied forms of wildlife in North America, was selected as the national emblem. By act of Congress, on June 20, 1782, a design for the national coat-of-arms displaying the bald eagle was adopted.

In a paper published by the Fish and Wildlife Service of the United States Department of the Interior*, Ralph H. Imler and E. R. Kalmbach have reviewed the economic status of the bird. Information has been assembled from reliable sources, from the examination of a series of stomachs and crops of bald eagles, and food remains at nests, to permit a current appraisal of the economics of the bird both within the borders of the United States and in the Territory of Alaska. Study of the economics of the bald eagle was prompted largely by the need for information to appraise the merits of bounty and other legislation affecting the eagle in the Territory of Alaska, where it long has been the subject of controversy. Although the bald eagle was noticeably reduced in south-eastern Alaska during the years of bounty payments after 1917, there are indications that the bird is now regaining its numbers and may again assume its former abundance in favoured areas.

As a basis for laboratory food studies, 435 stomachs of Alaskan bald eagles were collected and examined. In addition, data are available from thirty-one stomachs collected in the United States, and six stomachs collected in Canada. Nearly two-thirds of the food of Alaskan eagles was composed of fish, and of this about one-sixth (16·9 per cent) was salmon. Imler and Kalmbach believe that most of the salmon was carrion when found by the birds. An appreciable, but uncertain, portion of the other fish consumed was known to be dead when located by the eagles. Less than one-fifth (18·8 per cent) of the Alaskan eagles' food was derived from birds, the remainder being various marine species plentiful in the north Pacific.

Stomach examination has substantiated to a limited extent the reported predation of the bald eagle on deer. There is no evidence that the bald eagle exerts an appreciable effect on the population of small mammals unless it should be during winter when numbers of these birds may congregate in areas where jackrabbits are abundant.

Only in Alaska is the bald eagle abundant enough to constitute a significant hazard to domestic livestock, and even there its most important relation is with the semi-domesticated blue fox. During recent years, this problem has been materially alleviated, the more progressive raisers confining their animals under screens. Within the United States, the bald eagle has occasionally preyed on domestic poultry, but here again the small number it takes makes the total effect insignificant.

ORIGIN OF THE CHARACTERISTIC ENERGY LOSSES OF ELECTRONS IN SOLIDS

By Dr. E. J. STERNGLASS

Westinghouse Research Laboratories, Pittsburgh 35, Pennsylvania

THE characteristic energy losses of electrons passing through thin foils[1] have been interpreted in terms of collective oscillations by Bohm and Pines[2] and in terms of high-lying 'quasi-stationary' excited states by Hayasi[3]. It is the purpose of the present article to outline an alternative explanation in terms of individual atomic ionization and excitation processes according to the Bohr–Bethe theory for the stopping of charged particles.

On this interpretation, the principal energy loss occurring for all substances between approximately 12 and 22 eV. represents the ionization of the bound shell next to the valence-level, for which the binding energies range from about 10 to 20 eV. throughout the atomic table. The weaker loss lines below ~ 12 eV. are considered to represent excitations and ionizations of the valence electrons. As indicated schematically in Fig. 1, the ionization processes give rise to a characteristically asymmetrical energy loss peak of the same form as the known energy distribution curves of the secondary electrons[4]. The form of the secondary electron energy distribution curve and the location of the peak at about 2 eV. above the zero energy vacuum reference-level is predicted by the theory of ionization[5] and has been observed to be essentially the same for gases[6], metals[4] and insulators[4]. Since the half-width of these curves is only about 2–4 eV., the narrow peak is equivalent to a rather well-defined final state required to explain

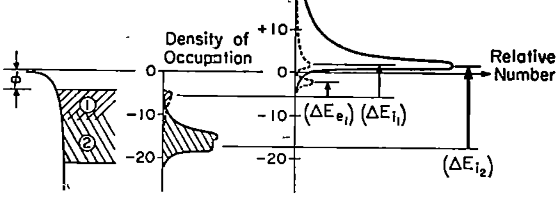

Fig. 1. Schematic diagram illustrating the fundamental energy-loss processes

the sharpness of the observed loss lines in some elements such as aluminium.

The dominance of the processes involving the bound shell next to the valence-level follows directly from the expression for the number of inelastic collision with a given shell per unit path-length according to the Bohr–Bethe theory. In the approximation used by Bohr[7], this quantity is given for the (n,l)-shell by the expression

$$s_{n,l} = \frac{2\pi\varepsilon^4 N}{V}\left[\frac{Z_{n,l}}{E_{n,l}}\ln\left(\frac{2V}{E_{n,l}}\right)\right] \qquad (1)$$

where V is the volt-energy of the incident electron of charge ε, N is the number of atoms per unit volume, $Z_{n,l}$ the number of electrons in the (n,l)-shell and $E_{n,l}$ is the excitation energy, roughly equal to its binding energy $I_{n,l}$.

Examination of equation 1 shows that for $V \gg E_{n,l}$, $s_{n,l}$ varies almost directly with $Z_{n,l}$ and inversely with $E_{n,l}$. It follows that especially in the heavier elements, the number of collision processes with the bound outer shells will dominate. Thus, for the case of copper, taking $E_{n,l}$ as approximately equal to $I_{n,l} + \overline{E}_{se}$, where $\overline{E}_{se}$ is the average energy carried away by a secondary ($\sim$ 6 eV.), one gets $E_{4s} \simeq 12$ eV. and $E_{3d} \simeq 23$ eV., making $s_{3d}/s_{4s} \simeq 5$. The same dominance of the interaction with bound electrons has recently been suggested as explaining the associated phenomenon of secondary electron emission[8].

Since transitions from the filled levels terminate predominantly in the continuum, the strongest energy-loss line corresponds to ionization or secondary electron formation from an outer bound shell. The most probable value of the associated energy loss (ΔE_{i_2}) would be expected to be a few eV. greater than the binding energy of the peak density point in the filled shell as determined by X-ray results. For the valence shell, excitation has a probability comparable to ionization, giving rise to an energy loss (ΔE_{e_1}) of the order of the work-function φ. The ionization of the valence shell itself must lead to a loss (ΔE_{i_1}) greater than φ by $\sim$2–4 eV.

It appears that all the observed losses of higher energies can be explained as simple multiples or combinations of the dominant three fundamental processes (ΔE_{e_1}), (ΔE_{i_1}) and (ΔE_{i_2}). Since the successive collisions are statistically independent, the relative weight of the various possible combinations is determined by simple probability considerations, which will govern the intensities of the higher energy-loss peaks.

The condition that all the observed loss peaks represent simple combinations of two or three fundamental losses is found to be remarkably well confirmed for all metals and insulators for which data are available[1]. As an example, the case of gold is presented in Table 1. The fit to the simple scheme so far as location of the peaks is concerned is surprisingly close, well within the experimental uncertainty of $\pm$ 2 eV. Furthermore, it should be noted that the particular combinations actually observed experimentally follow the pattern expected from probability considerations. Thus, there are never more than two events of small cross-section $(\Delta E_{e_1}$ and $\Delta E_{i_1})$ required to account for any peak and never more than three events of any type making up a single loss line, with the exception of the event with highest expected cross-section (ΔE_{i_2}), for which there are as many as four repetitions.

Table 1

The present explanation may be tested by calculating the expected form of the loss spectrum for the principal loss (ΔE_{i_2}) in the case of aluminium at two different energies. To obtain the relative contribution of each multiple collision, it is necessary to find the expected number of collisions $(s_{n,l})d$ in a thickness d from equation 1, and then to calculate the probability of the occurrence of 0,1,2,3 . . . collisions according to the Poisson distributing law. This has been done for aluminium using $E_{n,l} = I_{n,l} + \overline{E}_{se} = 19$ eV. and $Z_{n,l} = 2$ for the $3s$-shell, giving $\lambda_{n,l} = (s_{n,l})^{-1} = 140$ A. at 7·6 keV. and 460 A. at 30 keV. The resulting curves are shown in Fig. 2,

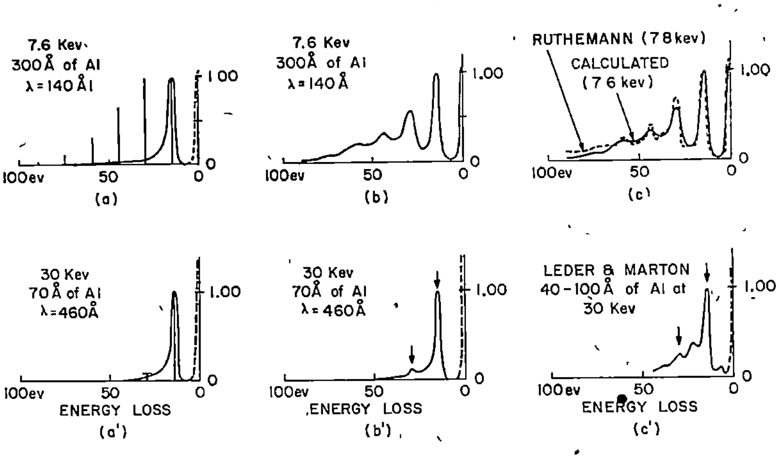

Fig. 2. Comparison of calculated and observed loss spectra in aluminium at two different energies. Curve (*a*) shows the assumed shape of the principal loss, and vertical lines the heights of which represent the expected numbers of single, double, triple, etc., events expected in a 300-A. layer. Curve (*b*) shows the sum of all the losses derived from repetition of the properly weighted principal loss curve of (*a*). Curve (*c*) shows the comparison with observed spectra. Curves a^1, b^1, c^1 are similarly derived for a thinner layer and higher bombarding voltage

calculated for $d = 300$ A. as used by Ruthemann[9] and $d = 70$ A. used by Leder and Marton[1]. The form of the fundamental loss curve (a) was taken from typical secondary electron energy spectra. The shapes of the higher order loss peaks were determined by carrying out a numerical convolution process weighted according to the Poisson distribution shown by the vertical lines in (a) and (a^1). It is seen that the calculated spectra due to the principal loss at 14·7 eV. satisfactorily reproduce the observed number of peaks as well as their relative amplitudes and shapes.

Although this agreement strongly supports the hypothesis that the observed losses represent combinations of only a few types of independent atomic collisions, thus making it unnecessary to postulate a whole series of high-lying 'quasi-stationary states'[3], it does not by itself rule out the explanation involving excitation of plasma oscillations[2]. This is due to the fact that the form of the expression for the mean free path obtained in plasma theory is essentially the same as that of equation 1, and that, for the case of aluminium, a quantum of the plasma oscillation has an energy roughly equal to $E_{n,l}$, while at the same time the number of valence electrons is very nearly equal to $Z_{n,l}$ for the $3s$-shell. As a result, plasma theory leads essentially to a similar mean-free-path and amplitude distribution in the loss spectrum for aluminium, although it must be noted that the characteristic asymmetry in the shape of the loss peaks does not seem to be explained by any simple plasma resonance mechanism.

A more definite distinction between the two proposed mechanisms can, however, be made in the case of the heavier elements, where $Z_{n,l}$ for the filled shells is much larger than the number of free conduction electrons. Thus, for the case of copper $(s_{n,l})^{-1} \simeq 80$ A. at 30 keV. according to equation 1, and $\simeq 760$ A. according to the plasma theory, using the usual assumption of one conduction electron per atom. Essentially the same situation holds for all the noble metals, so that according to plasma theory, one would not expect to find the high-order multiple loss-peaks in the case of gold (Table 1) for the energies and layer thicknesses used ($\sim$100–200 A.)[1]. Thus, to account for a loss peak at 60 eV. with a fundamental plasma loss $h\nu_{pl} = 9\cdot0$ eV.[9], approximately seven repeated events would have to occur. But this would require a mean-free-path at least ten times smaller than calculated from plasma theory.

Inasmuch as the collision cross-section for the bound outer shells cannot be expected to be affected strongly by changes in the state of aggregation or the bulk properties of the solid, it is also no longer surprising that characteristic losses of essentially similar type have been observed in metals and insulators. For the same reason, a crucial test that can clearly decide between the individual atomic and collective loss mechanisms would be provided by measurements on metal vapours.

In view of the close correlation of the characteristic losses with the fine-structures of X-ray absorption edges and short-wave limits noted by other investigators[1], it appears possible to explain these effects also in terms of the energy loss mechanism outlined above.

A more detailed discussion of this problem will be presented elsewhere. I am indebted to Mr. L. B. Leder and Drs. L. Marton, E. N. Adams, J. W. Coltman and R. L. Longini for helpful discussions of this problem.

GENETIC STUDIES OF THE RELATIONSHIP OF TUMOUR—HOST CELLS

Detection of an Allelic Difference at a Single Gene Locus in a Small Fraction of a Large Tumour-Cell Population

A SERIES of experiments is being carried out in this laboratory with the view of inducing mutations at certain gene loci in tumour cells, either by non-specific means such as X-rays, or in a more specific way by treatment with deoxyribonucleic acid of specific origin. The basic material of this study consists of tumours induced in F_1 hybrid mice, produced by crossing the inbred A-strain with one of the three isogenic sublines $A.SW$, $A.BY$ or $A.CA$ (kindly provided by Dr. G. D. Snell). These sublines have been developed by Snell[1,2], and they are known to differ from the A-strain by one gene only, having a different allele at the histocompatibility-2 (H-2) locus. This difference makes all three sublines resistant against grafted tissues and tumours of all other sublines and the A-strain itself, in spite of their genetic identity with regard to all or most other loci.

An F_1 hybrid produced by crossing the A-strain with one of the isogenic resistant sublines is theoretically homozygous with respect to all loci except H-2, which presents the heterozygous condition. Tumours arising in such F_1 hybrids should be transplantable to other F_1 hybrids of the same genetic composition, but not to any of the parental sublines, since the latter would be able to produce a homograft reaction against the antigenic products of the foreign H-2 allele derived from the other parental subline and contained in the tumour cells in a single dose.

We have induced a series of sarcomas in such F_1 hybrids by methylcholanthrene. The majority of these tumours was found to behave according to expectation and with great rigidity. There were some exceptional tumours, however, that grew in one or both parental strains from the beginning or after

a few generations of transfer. These were excluded from the present experiments.

The 'stable' tumours that grow only in F_1 hybrids of the original genetic composition would lend themselves ideally to mutation studies (compare ref. 3), provided that certain basic conditions can be fulfilled. A tumour arising in an $A \times A.SW\ F_1$ hybrid (genotype: $H\text{-}2^aH\text{-}2^s$) would be unable to grow in the parental A-line (genotype $H\text{-}2^aH\text{-}2^a$), unless a mutation occurred from $H\text{-}2^s$ to $H\text{-}2^a$ in one of the tumour cells. Such a mutant would have an absolute selective advantage when the population is tested for growth in the A-strain, where it would give rise to a progressively growing tumour, while all cells of the original type would be destroyed by the host. It would be still quite unable to grow in the other parental line ($A.SW$, genotype $H\text{-}2^sH\text{-}2^s$). Such a system would have the unique quality of making detectable a single gene mutation occurring in a single cell within a large neoplastic cell population.

It is not *a priori* certain, however, that the mutant would be able to survive under conditions in which the rest of the inoculated population, usually consisting of several million cells, is being destroyed simultaneously by an intensive and efficient host reaction. In spite of its favourable genetic composition, the mutant cell or its derived clone may be damaged by the host reaction or by toxic products of the damaged and killed tumour cells in a non-specific way. If this were the case, rare mutations would scarcely be detectable in such a system. Because of this possibility, it was considered necessary to carry out model experiments in order to investigate the survival of known mixtures of compatible and incompatible tumour cells, differing by a single allele at the H-2 locus, after inoculation into mice of known genotype. The main results are described here.

Sarcomas induced by the subcutaneous injection of methylcholanthrene were used in their early transfer generations (less than 10). Cell suspensions were made by forcing the freshly removed, ice-cooled tumour tissue through stainless steel nets into Krebs–Ringer-phosphate solution, containing 0·25 per cent gelatin and 0·5 per cent glucose. Cells were enumerated in a hæmocytometer and appropriate dilutions were made in the same solution. A known large number of tumour cells that had originated in an $A \times A.SW\ F_1$ hybrid were then mixed with a known small number of similarly suspended cells derived from the parental A-strain. The mixtures were inoculated subcutaneously into A mice. Control A mice were inoculated either with cells of the F_1 tumour alone or with cells of the A tumour alone. The same cell dosages were used in the controls as there were in each of the mixed inocula. Mice of both sexes were used, weighing 20–25 gm. They were all derived from the single-line inbred nucleus of the strain, kept by continuous brother-to-sister mating. The inoculated animals were observed for tumour formation by regular palpations, followed by calliper measurements of the progressively growing neoplasms and by recording the time elapsing until the death of the host from the tumour. Mice without tumours were considered negative after an observation period of four months.

The results of some representative experiments are shown in Table 1. It appears that even in cases where the compatible ($H\text{-}2^aH\text{-}2^a$) fraction of the inoculated cell population was as small as 4×10^{-7}, it survived not only as well as, but even much better than, in the controls, in spite of the simultaneous destruction of the overwhelming majority (genotype: $H\text{-}2^aH\text{-}2^s$) by the intense homograft reaction of the $H\text{-}2^aH\text{-}2^a$ host. Indeed, it seems as if the former cell type would have been stimulated in its growth considerably by some factor involved in the destruction of the latter. This was manifested by an increased percentage of mice killed by progressively growing tumours, and by a more rapid development of the neoplasms and a reduced survival time of the tumour-bearing animals, when mice receiving the mixture of compatible and incompatible cells were compared with animals inoculated with the same number of compatible cells alone. The mechanism of this stimulating effect is not clear. It could be due conceivably to products liberated by the incompatible tumour cells in the course of their destruction or to the homograft reaction itself. A similar stimulating effect has been found by Révész[4] in experiments in which mixtures of living tumour cells and cells of the same tumour line but killed by X-rays were inoculated into compatible hosts. Since his system also involves, besides disintegration of killed cells, an intense inflammatory reaction of the host, it does not distinguish between the possibilities of stimulation by cell products or by the host response.

The stimulating effect does not seem to be specific for the cells of the $H\text{-}2^aH\text{-}2^s$ genotype, or for methylcholanthrene-induced homologous tumours, since it occurred in a similar fashion when a small number of *S4A* tumour cells, indigenous to the A-strain, were mixed with a large proportion of cells derived from a mammary carcinoma of the *DBA* strain, and inoculated into *A*-mice. Preliminary experiments indicate that there is no stimulating (or inhibiting) effect if the compatible and incompatible cells respectively are inoculated at two different sites in the same recipient animal. Further studies on the mechanism of the stimulating effect are in progress.

These findings have three main implications. First, they emphasize the extreme specificity exhibited by the homograft reaction and its ability to 'recognize' a very small number of cells of compatible genotype within a large population of incompatible cells of similar morphological origin and differing from the former only with regard to a single gene locus. Second, they justify the expectation that the present tumour–host system will enable the detection of a single mutation at a single histo-compatibility locus in a single tumour cell. Finally, similarly to the experiments of Révész[4], they indicate that the destruction of a very large proportion of a tumour-cell population does not necessarily lead to the damage of the small surviving fraction, provided that the latter is genetically compatible with the host. The disintegration of the damaged cell fraction and the ensuing inflammatory response do not seem to increase the chances of the host destroying the surviving part of the population and being cured; on the contrary, they stimulate its growth. It seems that the host has no effective way of reacting against tumour cells of compatible genetic constitution, either in a specific or a non-specific way, at least when considering host–tumour systems similar to those used in the present experiments.

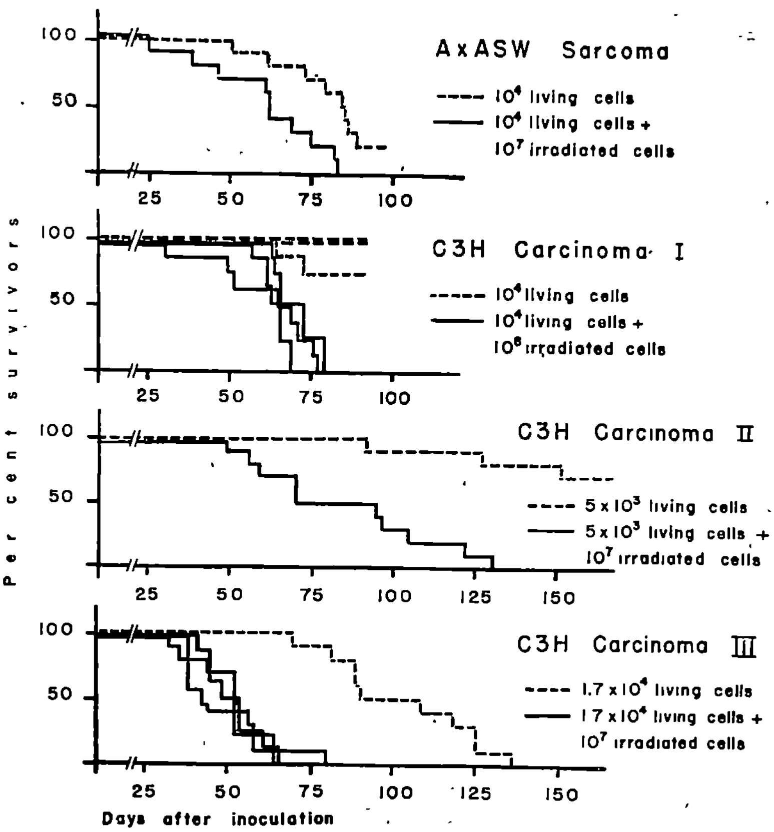

Fig. 1. Effect of cells lethally damaged by X-rays on admixed viable cells. Note higher incidence of progressively growing tumours and a reduction of survival-time in animals inoculated with mixture. Four different tumours were inoculated into mice of the original genotype

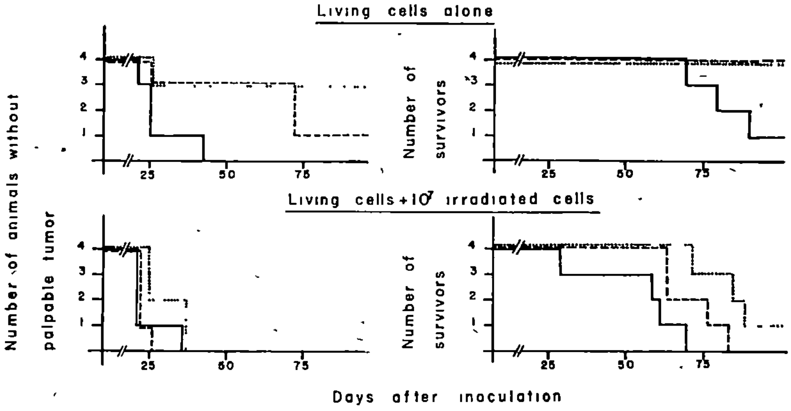
Effect of Tumour Cells killed by X-rays upon the Growth of Admixed Viable Cells

Tumours irradiated with sublethal X-ray doses can be schematically considered as containing two kinds of tumour cells, differing in their prospective reproductive potentialities. One fraction has been damaged irreversibly so as to lose the ability for continued reproduction. These cells may die immediately or after a number of cell divisions[1]. Another part of the cell population is composed of cells undamaged or damaged in a reversible way, and still capable of multiplying serially without restraint. The relative proportion of these two fractions is probably related to the X-ray dose, the inherent sensitivity of the cells and to various environmental conditions during irradiation.

Very little is known about the potential influence that the lethally damaged population may exert on the continued proliferation of the surviving fraction, either directly or through the host organism. It is conceivable that the dying cells may stimulate the growth of the survivors in a variety of ways; but it is equally possible that they inhibit them by toxic products or as a result of the intense local inflammatory reaction they induce in the host.

The problem was approached experimentally by mixing irreversibly damaged and viable mouse tumour cells in various proportions. Two main tumour types were used. The first group includes neoplasms that arose spontaneously or have been induced by carcinogens in mice of highly inbred strains or in F_1 hybrids produced by crossing two inbred strains. These tumours were used after a single generation of transfer into mice of the original genotype. Another category is represented by the Ehrlich ascites tumour that originated in a mouse of



——, 5×10^3 living cells; – – –, 5×10^2 living cells; ......, 5×10 living cells

Fig. 2. Effect of cells lethally damaged by X-rays on the growth of viable cells admixed in various numbers. A spontaneous mammary carcinoma of the *C3H* strain was used. The curves on the left show the appearance of palpable tumours; those on the right denote survival time. Note higher incidence of tumours, reduced latency-period and decrease of survival-time in animals receiving the mixture

unknown genetic composition and has been carried in heterozygous animals for sixty years.

The various solid tumours were brought into suspension by forcing the freshly removed, ice-cold tumour tissue through stainless steel screens into a solution of Krebs–Ringer phosphate, containing 0·25 per cent gelatin and 0·5 per cent glucose. The cells were enumerated in a hæmocytometer and appropriate dilutions were made with the same solution. The Ehrlich ascites tumour was used in its natural suspension form. One aliquot of each suspension was irradiated *in vitro* with 12,000 r. in a nitrogen atmosphere, a dose far above what is necessary for the complete inactivation of all tumours used in the present study. A known number of irradiated cells was mixed in various proportions with an untreated aliquot of the same suspension. Three groups of mice were inoculated. Group *A* (6–10 mice) received only lethally damaged cells. Group *B* (10–30 mice) was inoculated with untreated cells alone. Group *C* (10–30 mice) received mixtures of the two cell types in various proportions. The number of lethally damaged cells was kept constant, and the untreated cells were admixed in the same number as used for the inoculation of group *B*. The latency-period elapsing before the appearance of palpable tumours was determined and the survival-time of the tumour-bearing animals was recorded. Mice surviving without tumours were kept under observation for three to six months. In the case of the Ehrlich ascites tumour, the total number of free tumour cells in the peritoneal cavity was also followed by quantitative growth curves[2].

No growth was obtained in any mouse belonging to group *A*. When comparing groups *B* and *C*, the lethally damaged cells were found to exert an intense stimulating effect on the proliferation of viable tumour cells of the first category (consisting of four different spontaneous mammary carcinomas of the *C3H* strain and a methylcholanthrene-induced sarcoma of the $A \times ASW\ F_1$ hybrid combination). This was most apparent when the number of viable cells was small (10^2–10^3) compared to the number of damaged cells (about 10^7). In such cases, group *C* showed a reduced latency-period and a decreased survival-time of the tumour-bearing animals when compared to group *B* (Figs. 1 and 2).

Different results were obtained with the Ehrlich ascites tumour[2]. When measuring the growth curve of intraperitoneally inoculated tumour cells, an analogous stimulation was found upon mixing 2×10^6 living cells with 20×10^6 lethally damaged cells. If a small viable inoculum was used instead (100 cells) and the number of damaged cells was kept constant, a pronounced inhibition was observed, however. While 100 cells alone led to progressively growing tumours in all mice, the presence of dead cells completely prevented their development. This was found to be due to an active immunization of the host against the immunogenetically foreign Ehrlich tumour by the cells damaged by X-rays, thus preventing the small viable fraction from reaching an irreversible population-level.

These findings indicate that fallacious results may be obtained with so-called non-specific tumours that grow in genetically foreign hosts. A treatment that damages only one part of the cell population may lead to tumour regression after receiving help from the histo-incompatibility reaction of the mouse. This agrees in principle with the findings of Cohen and Cohen[3]. A similar situation does not seem to occur with an immunogenetically compatible tumour–host system, where partial damage of the population appears to stimulate the growth of the survivors in all cases. This occurs in spite of the fact that the host reacts with an intense and histologically very impressive local inflammatory reaction against the presence of damaged and killed tumour cells[4]. This reaction is nevertheless unable to destroy, or substantially damage, compatible and viable tumour cells. In this respect it is similar to the homograft reaction[5].

In our continued studies about the nature of the stimulating effect exerted by dead cells we are trying to distinguish between the following possibilities: (1) specific stimulation by homologous cell products[6]; (2) a 'feeder effect'[7], in which the dead cells release essential nutrients; and (3) stimulation through provoking an inflammatory response and/or vascularization from the side of the host.

I wish to thank Dr. G. Klein for many valuable discussions, and Miss L. Hennings for her assistance in the experimental work. This work was supported by grants to Dr. G. Klein from the Swedish Cancer Society and Konung Gustaf V:s Jubileumsfond.

Incorporation of Radioactive Aspartic Acid into the Proteins and Related Fractions in Mice bearing the Ehrlich Ascites Carcinoma

In Zamecnik's laboratory, Frantz *et al.*[1], using dinitrophenol, found in liver slices a parallelism between the inhibition of phosphorylation and of amino-acid incorporation. Siekevitz[2] demonstrated in a cell-free system a relation between oxidative phosphorylation and amino-acid incorporation in a crude rat-liver homogenate. Hoagland[3] concluded from his experiments that the carboxyl groups of the amino-acids are activated by adenosine triphosphate, and that the activated amino-acyl groups are bound through an adenosine monophosphate bridge to an enzyme acting as an intermediate amino-acyl transfer compound. However, such intermediates have not yet been isolated and identified. In their systems it was not possible to 'exchange out' the carbon-14 labelled amino-acids with large quantities of unlabelled amino-acids; thus the incorporation was different from the exchange process described by Gale and Folkes[4] in fragmented *Staphylococcus aureus*. J. T. Park[5] has isolated uridine-5′-phosphate derivatives containing an amino-sugar and amino-acids from extracts of *Staphylococcus aureus* treated with penicillin. On the basis of these and a great number of other experiments, Borsook[6] proposed a hypothesis for the mechanism of biosynthesis: the carboxyl groups of free amino-acids are first activated by an enzyme system dependent on adenosine triphosphate. They are then transported to a nucleic acid template by an unknown mechanism and are arranged in a specific sequence, the amino-acids being attached to the phosphate of nucleic acid by their carboxyl groups. On this template, the amino-acids are then linked by peptide bonds through the action of another enzyme, and the protein molecule peels off the template.

The following work is an attempt to find and investigate any labelled compounds of relatively low molecular weight which might be formed on administration of a ^{14}C-labelled amino-acid to mice bearing the Ehrlich ascites carcinoma. The tumours were produced by intraperitoneal transfer of approximately 10^7 tumour cells into each mouse from stock mice (C_{57}Black × C_3HF_1). After the tumour has grown for four days, 0·1 ml. of a solution of L-aspartic acid-^{14}C (generally labelled, Radiochemical Centre, Amersham) containing 8·33 μc. (in 0·16 mgm.) was injected intraperitoneally into each of the ten mice.

The mice were killed 15 min. after the injection, the livers pooled and kept at −78° C., and from the ascitic fluid the tumour cells were separated by a short centrifugation at 0°, and were then mixed with an equal volume of 0·66 N perchloric acid at 0°. After homogenizing and standing for 3 hr. at 0°, the precipitate was centrifuged off and the supernatant neutralized with potassium hydroxide at 0°. After the potassium perchlorate was centrifuged off, a clear, neutral solution was obtained, practically free of perchloric acid (1 per cent). This solution will be called the cell extract. In a similar way a liver extract was obtained from the pooled livers.

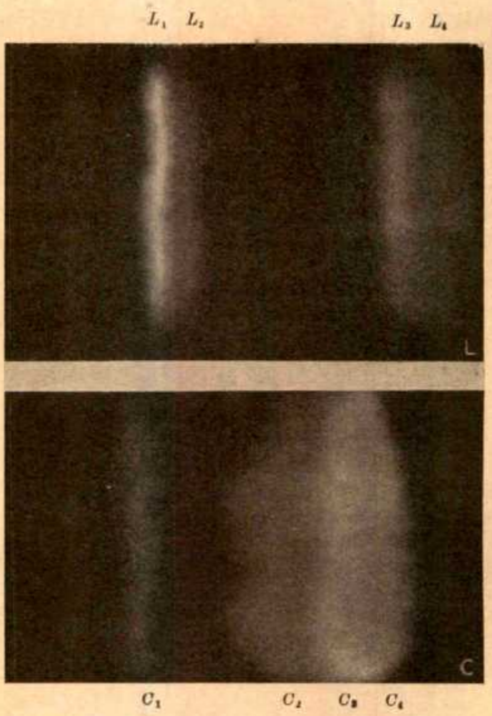

Fig. 1. Autoradiograms of the electrophorograms of the liver extract (L) and the cell extract (C)

These extracts were submitted to paper electrophoresis*(Whatman 3 *MM*, veronal buffer *p*H 8·6, 300 V./12 m.amp. = 10 V./cm., 210 min.). After drying in a current of warm air (40°), autoradiography revealed four labelled zones moving to the positive pole (Fig. 1).

It is interesting to note the differences in the strength and the electrophoretic mobility of the fractions L_2 and C_2; although, at this stage, it is not certain that this difference can be attributed to a particular state of the mechanism of biosynthesis in the tumour cell.

Zone L_4 was eluted and was run in ammonium sulphate–*iso*propanol[7]. The ultra-violet print shows two spots with R_F 0·37 and 0·81 respectively. Autoradiography showed that only the spot with R_F 0·81 contained carbon-14 activity. This spot on hydrolysis with N hydrochloric acid (100°, 1 hr.) gave a substance which ran in *iso*propanol.hydrochloric acid[8] with the same speed as uridylic acid (R_F 0·63) and had the same ultra-violet spectrum in neutral, acid and alkaline solution. It also gave a ninhydrin-positive spot which ran with the same speed (R_F 0·36) as aspartic acid in this same solvent. The carbon-14 activity was contained in the aspartic acid spot, while the uridylic acid spot was inactive. The other spot (R_F 0·37 in ammonium sulphate–*iso*propanol), which did not contain carbon-14 activity, was identified as adenylic acid.

Zone L_3 gave in ammonium sulphate/*iso*propanol two spots with R_F 0·38 and 0·70 respectively. All the carbon-14 activity was contained in the R_F 0·70 spot. It had the same ultra-violet spectrum as uridylic acid. In *tert*-butanol/hydrochloric acid[9] the spot runs with the front, whereas uridylic acid under the same conditions has R_F 0·78.

In conclusion, both zones L_4 and L_3 contain inactive adenylic acid, while the carbon-14 activity is contained in a uridylic acid–aspartic acid compound, which in the substance of zone L_4 has R_F 0·81 and in that of zone L_3 has R_F 0·70 when run under the same conditions.

A proof of the constitution of the uridylic acid–aspartic acid compounds must await the results of further investigations at present in progress. The identification of the other zones obtained by electrophoresis is also proceeding. Fuller details, together with a consideration of possible biochemical implications, will be given in another paper.

Identity of the Phosphodiesterase and Deoxyribonuclease in Rattle-Snake Venom

As part of a programme on different phosphoesterases, the behaviour of the phosphodiesterase activity in rattle-snake venom has been studied by anion exchange chromatography. The adsorbent was the diethylaminoethyl cellulose of Sober and Peterson[1], and in order to utilize possible displacement effects a one-step-elution technique was used. This procedure has been applied earlier for the detection and separation of two acid phosphomonoesterases from horse radish[2,3]. However, the chromatographic experiments described here differ owing to the fact that we now have been working at a pH near the pK of the ion exchanger[1]. Although the investigation is being continued, this communication may be justified by two unexpected findings: the venom seems to contain two phosphodiesterases and both of them digest deoxyribonucleic acid.

A typical experiment, pointing toward these conclusions, was carried out in the following way. A column (22 cm. × 1·04 cm.) with 19 ml. of diethylaminoethyl cellulose was brought into equilibrium with 0·02 *M* tris(hydroxymethyl)aminomethane – hydrochloric acid buffer[4] ('Sigma 7–9, biochemical buffer', Sigma Chemical Co., St. Louis 18, Mo.) of pH 8·9 (the starting buffer). Of the freeze-dried venom from *Crotalus adamanteus* (Ross Allen's Reptile Institute, Silver Springs, Florida), 40 mgm. was dissolved in 2 ml. of starting buffer. After centrifugation, which removes some less-soluble globulin material, the solution was applied to the column. The chromatogram was then developed with a 0·33 *M* tris(hydroxymethyl)aminomethane – hydrochloric acid buffer of pH 8·9 using a water pressure of 28 cm. The first 2 ml. were discarded and fractions were then collected every 8 min. with volumes of around 0·8 ml. The temperature was 4°.

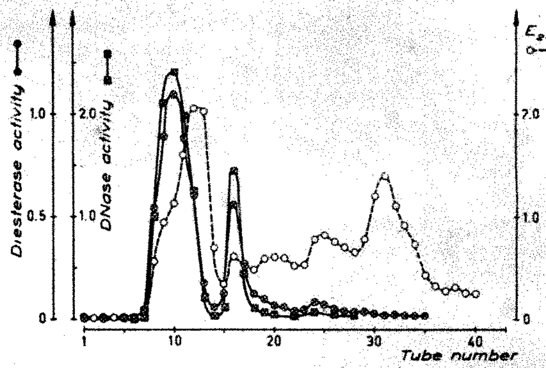

Fig. 1. Chromatography of rattle-snake venom on diethylaminoethyl cellulose. Open circles represent extinction at 280 mμ, crossed circles the activity toward calcium (bis(*p*-nitrophenyl)-phosphate)$_2$ expressed as millimoles of nitrophenol liberated per l. of incubation mixture and crossed squares the deoxyribonuclease activity expressed as liberated extinction at 260 mμ

The effluent was analysed for protein content, measured as extinction at 280 mμ in a Beckman *DU* spectrophotometer, and for phosphodiesterase and deoxyribonuclease activity. Calcium (bis(*p*-nitrophenyl)-phosphate)$_2$ (for preparation, see ref. 5) was used as substrate for the diesterase activity and the procedure was the same as that utilized for the determination of a monoesterase[6].

The deoxyribonuclease activity was estimated as the acid-soluble nucleotide material liberated from a 0·6 per cent solution of deoxyribonucleic acid, prepared according to Kay *et al.*[7], and dialysed against 0·05 *M* tris(hydroxymethyl)aminomethane–hydrochloric acid buffer of pH 8·9. Of this substrate solution, 100 μl. was incubated with 25 μl. from the different fractions for 60 min. at 37°. The reaction was stopped with 1 ml. of 0·01 *M* lanthanum nitrate in 0·1 *M* hydrochloric acid; the precipitated deoxyribonucleic acid was centrifuged down and the extinction at 260 mμ of the supernatant fluid read against a blank was taken as the deoxyribonuclease activity.

The result from this experiment is shown in Fig. 1. As can be seen, both phosphodiesterase and the deoxyribonuclease activities (crossed circles and crossed squares, respectively) show two almost coinciding peaks. The question whether or not these two peaks correspond to two different enzymes will be discussed elsewhere together with additional chromatographic experiments.

The possible identity of the phosphodiesterase and the deoxyribonuclease activities is indicated by the striking coincidence of the curves in Fig. 1, which is even better than the figure shows. This depends on the fact that, while the splitting of calcium (bis(*p*-nitrophenyl)phosphate)$_2$ follows a straight line with increasing amount of enzyme, the corresponding relation for the digestion of deoxyribonucleic acid has a lag part in the beginning.

The coincidence has been confirmed in another chromatographic experiment, in which the conditions were only slightly different from the experiment shown in Fig. 1, but using as substrate deoxyribonucleic acid prepared according to Hammarsten–Sevag[8,9]. Preliminary determinations have also shown the pH optimum for the deoxyribonuclease activity to be around 9, which is similar to the optimum of the diesterase activity.

Table 1. HEAT INACTIVATION OF DEOXYRIBONUCLEASE AND PHOSPHODIESTERASE ACTIVITY (ARBITRARY UNITS)

75	764 780	608 666	1·21			
90	750 737	616 622	1·20			

The classical view on the enzymatic degradation of deoxyribonucleic acid[10] has been that an enzyme called deoxyribonuclease acts on the macro molecule, splitting it mainly into oligonucleotides. Another enzyme, named phosphodiesterase, then acts on the oligonucleotides, hydrolysing them nearly completely to mononucleotides.

However, the specificity of different phosphodiesterases has been a subject of discussion. Privat De Garilhe and Laskowski[5] pointed out that their purified phosphodiesterase from rattle-snake venom acts on both calcium(bis(p-nitrophenyl)phosphate)$_2$ and oligonucleotides, but that no action could be observed toward "a highly polymerized DNA". Brawerman and Chargaff[11], when studying barley phosphodiesterase, doubt that the same enzyme is acting on different substrates of low molecular weight, while Schmidt[10] classified the phosphodiesterase from different venoms as "unspecific".

As mentioned earlier[2], the chromatographic procedure used here gives only a preliminary group separation and, therefore, a limited degree of purification. The enzyme studied by Privat De Garilhe and Laskowski[5], which should be identical with ours, is probably purer than our preparation. It might thus be possible that our enzyme preparation contains two different enzymes, one acting on deoxyribonucleic acid and one on calcium(bis(p-nitrophenyl)phosphate)$_2$.

In order to check this hypothesis the heat inactivation of the phosphodiesterase and deoxyribonuclease activities has been followed. Chromatographically purified samples, similar to the one in tube 10, Fig. 1, were kept at temperatures between 50° and 58°, and at different times samples were taken out and incubated with the two substrates. The experiment at 50° showed no measurable inactivation, while at 58° precipitation caused difficulties in obtaining reproducible figures for the activities. The results from two other series are given in Table 1.

The coincident inactivation demonstrated here, together with the striking parallelism between the two activity curves in Fig. 1, thus indicate that the same enzyme is responsible for the action on both calcium(bis(p-nitrophenyl)phosphate)$_2$ and macromolecular deoxyribonucleic acid.

This investigation is financially supported by grants from the Rockefeller Foundation and the Swedish Cancer Society.

We wish to express our thanks to Profs. E. Hammarsten and A. Tiselius for their stimulating interest.

Sialoadenectomy and Thyroid Response to Thyrotrophic Hormone

PREVIOUS observations[1-3] have been reported which indicated the salivary glands to be capable of modifying thyroid activity such modification being made apparent by a reduced iodine-131 uptake, reduced turnover rate and a reduction in the thyroid-stimulating hormone titre as determined by the method of Barell and Holmgren[4]. Since sialoadenectomy imposed upon hypophysectomized rats did not result in different thyroid activities[2], it was postulated that the salivary glands, that is, substance(s) elaborated therefrom, could act upon the thyroid (1) in conjunction with the hypophysis (synergistic action) or (2) upon the hypophysis directly. In an attempt to learn something of the mode of action of the salivary-gland secretions on thyroid activity, the response of sialoadenectomized, hypophysectomized and intact animals to parenteral thyroid-stimulating hormone was studied. Animal feeding, care, size, strain, pre- and post-operative treatment were as previously described[1-3]. There were not less than eight and no more than twelve rats in any experimental or control group. The radioactivity assays were performed in the same manner as they were in previous studies.

Preliminary experimentation (Table 1) showed that the thyroids of intact rats would take up 16·3 per cent more phosphorus-32 when treated with thyroid-stimulating hormone (50 μgm. per 100 gm. body-weight), whereas the thyroids of sialoadenectomized rats take up 53·7 per cent more phosphorus-32 than do their non-treated controls in response to the same dose. A second experiment was performed, the results of which are indicated in Table 2. Thyrotrophic hormone increased the phosphorus-32 activity in the intact animal thyroids 14·2 per cent over base-line values; in the sialex animals a 132 per cent increase was observed with the 50 μgm. dose, whereas with a 100 μgm. dose,

Hypophysectomized + sialoadenectomized	24·8 ± 1·6

* Standard error of the mean

Table 3. COMPARISON OF THE AVERAGE WEIGHT OF RAT THYROIDS

Group	Average thyroid weight (mgm.)	P value compared with controls
Intact controls	14·0 ± 0·7*	—
Sialoadenectomized	12·1 ± 0·3	0·018
Hypophysectomized	11·7 ± 0·5	0·015
Hypox + sialex	11·9 ± 0·6	0·030

* Standard error of the mean

a 341 per cent increase was noted. Hypophysectomized animals responded to thyroid-stimulating hormone in the manner expected, showing a 472 per cent increase in phosphorus-32 activity in the thyroid. The titre of thyroid-stimulating hormone in hypophysectomized–sialoadenectomized rats was found to be essentially the same as that of hypophysectomized rats, an observation in agreement with previous findings[3]. The data presented thus far are indicative of some regulatory function of the secretions of the salivary glands on thyroid activity, probably involving the control of the action of thyroid-stimulating hormone on thyroid tissue or by an effect on the thyroid cells which prepares them for the action of the hormone. The greater response of sialoadenectomized animals to the hormone, we feel, indicates that there is such a controlling mechanism. However, the role of the hypophysis appears to be dominant in the processes involved since its removal greatly reduces the observable effects of sialoadenectomy. It is quite obvious that the secretions of both glands must complement each other in sequential or parallel actions.

Analysis of the average weights of the thyroids from animals of comparable size discloses an interesting and collaborative observation. As indicated in Table 3, a significant difference appears to exist between the sizes of the thyroids of intact, sialoadenectomized, hypophysectomized and hypophysectomized–sialoadenectomized rats. Whether these changes are due to a relationship between the hormones or to metabolic disturbances induced by alterations in hormone patterns is not yet known[5].

This study was sponsored by a grant (C-1881) from the National Institutes of Health, Bethesda.

Antifibromatogenic Potency of 9α-fluoro Derivatives of Progesterone

THE use of halogenated pregnene derivatives, especially of 9α-fluoro-hydrocortisone, has been undoubtedly the greatest recent advance in the experimental pharmacology of steroids, as evidenced by the outstanding work of Fried and his colleagues[1] on the various potencies of this corticoid. In the present communication we discuss results obtained in guinea pigs, in which we tried to prevent the abdominal fibromatogenic action of œstrogen; other antiœstrogenic potencies also have been studied.

Antifibromatogenic activity and likewise other antiœstrogenic potencies of progesterone are known to diminish when oxidation is performed[2] at C_{21}, C_{11} and C_{17}. Diminution of these potencies is striking with oxidation at C_{11} (11β-hydroxyprogesterone) and, even more pronouncedly, with oxidation at C_{17} (17α-hydroxyprogesterone)[3]. How will the 9α-fluoro-derivatives of these compounds behave?

Pellets containing 20–80 per cent of 9α-fluoro-11β-hydroxyprogesterone mixed with cholesterol were implanted beneath the skin of castrated female guinea pigs. Pellets of œstradiol also were implanted. Complete inhibition of large abdominal fibroids was

* Absorption per day was calculated from loss of weight of the pellet during the experiment, on the assumption of non-selective absorption, as with the mixture of non-halogenated steroids (ref. 7). Fluorine was determined by the micromethod of Kolthoff and Slamsby (ref. 8). The method was not sufficient to establish any difference or lack of difference between the percentage of fluorine in non-used and used tablets. But the comparative figures of absorption per day in column 4 are not in favour of selective absorption. On the assumption of selective absorption, these figures should be multiplied by 5, with 20 per cent pellets (11 μgm./day); by 2·5, with 40 per cent pellets (20 μgm./day); by 1·25 with 80 per cent pellets (80 μgm./day); a drop from 80 μgm./day with 80 per cent pellets to 20, and 11 μgm./day with 40 per cent and 20 per cent pellets, is not possible with selective absorption (ref. 7).

† Range: 1·8–2·6 μgm./day.

obtained with as little as 2·2 (1·8–2·6) μgm./day of the halogenated compound (Table 1; Fig. 2). An average of 15 μgm. of progesterone was necessary to produce a similar effect[3,4]. Thus, the antifibromatogenic potency of 9α-fluoro-11β-hydroxyprogesterone is about six to seven times that of progesterone. But the increase of activity through halogenation appears to be even more striking when comparing 9α-fluoro-11β-hydroxyprogesterone with 11β-hydroxyprogesterone. With as much as 78 and even 490 μgm./day of the latter, prevention is still less pronounced than with 2·2 μgm. of the 9α-fluoro-compound (Table 2; comp. also Figs. 1 and 2). Halogenation with fluorine increases antifibromatogenic activity about two hundred times. (Should the assumption of non-selective absorption (see Table 1) be erroneous, increase of potency through halogenation with fluorine would be only about fifty times.)

As to the antihysterotrophic potency, the difference between the two compounds is not so striking, but also fully evident: with an average of 8 μgm./day of 9α-fluoro-11β-hydroxyprogesterone, the same antihysterotrophic effect is obtained as with 78 μgm./day of the non-halogenated compound[2]. It was the same with the antiluteinizing action (unpublished work). An increase of the antihysterotrophic activity of 11β-hydroxyprogesterone through halogenation had already been demonstrated in the extensive work of Huggins and Jensen[5] with the uterus of hypophysectomized rats. A considerably greater effect was obtained by these authorities with the injection of 250 μgm./day of the fluoro-compound than with the injection of 1,000 μgm./day of the non-halogenated compound.

Experiments were performed also with 9α-fluoro-11β,17α-dihydroxyprogesterone. As seen from Table 1, the antifibromatogenic and antihysterotrophic potencies of this compound are greatly inferior to those of 9α-fluoro-11β-hydroxyprogesterone. No prevention of the fibromatogenic or hysterotrophic action of œstrogen was obtained with as much as 56 μgm./day, that is, with an amount twenty to thirty times greater than the already highly active dose of 9α-fluoro-11β-hydroxyprogesterone (1·8–2·6 μgm./day). This finding gives new evidence of the deleterious influence of oxidation at C_{17} in the α-position on the antiœstrogenic potencies of progesterone derivatives (comp. Figs. 2 and 3), an influence which was already so evident with 17α-hydroxyprogesterone[3]. Indeed, an antihysterotrophic activity has been obtained in the rat with large quantities of 9α-fluoro-hydrocortisone[5,6], that is, notwithstanding the presence of OH in C_{17}-α.

Table 2. COMPARATIVE ANTIFIBROMATOGENIC POTENCY OF THREE STEROIDS IN GUINEA PIGS

	Antifibromatogenic steroid	μgm. per day	Fibrous tumoral effect	Coeff. Q_{2-3}	Antifibromatogenic potency
A	Progesterone (ref. 4)	9 15	3·6 1·5	1 0	1·00
B	9α-fluoro-11β-hydroxyprogesterone	2·2	1·3	0	6·00–7·00
C	11β-hydroxyprogesterone (ref. 2)	78 490	2·7 2·2	0·7 0·2	<0·03

The enormous increase of the antifibromatogenic activity due to halogenation with fluorine justifies the question whether use of this procedure could be used in trials with the antifibromatogenic and antitumorigenic action of steroids in those cases in which hitherto progesterone has been used. Similar clinical trials would be apparently handicapped by the fact that 9α-fluoro-11β-hydroxyprogesterone has also cortical activities[1].

Thanks are due to Dr. Josef Fried, of the Squibb Institute for Medical Research, New Brunswick, N.J., for a generous supply of halogenated pregnene derivatives.

Demonstration of Acetylcholinesterase on Motor End-plates after embedding in Polyethylene Glycol

Polyethylene glycol seems to be particularly suitable as an embedding medium for demonstrating several enzymes. Certain polyethylene glycols and their monostearates (polyethylene glycol 1,000 and 'Nonex 63', both obtainable from Gemec Chemicals Co., 120 Moorgate, London, E.C.2 ; 'Polywachs 1,000' and 'Produkt V 2,275'. both manufactured by C. W. H. Marl, Kreis Recklinghausen, Germany) are available as wax-like compounds, which in consistency strongly resemble paraffin, but have a lower melting point and are soluble in water, are very suitable for demonstrating non- or slightly diffusible enzymes. The polyethylene glycol embedding has the great advantage over paraffin embedding that the procedure takes only a short period of time (4–5 hr.) and the enzyme is exposed for 2–3 hr. at 42° C. In addition, substances such as ethanol which may inactivate the enzymes can be avoided.

The histochemical localization of acetylcholinesterase was studied on the motor end-plates of the guinea pig's intercostal muscle. Polyethylene glycol embedding was performed by the method of Miles and Linder[1], and the Koelle acetylthiocholine iodide method modified by Gerebtzoff[2] was used to demonstrate acetylcholinesterase. The intensity of the reaction seems to be quite satisfactory, structural details are well distinguished, and diffusion artefacts are negligible even after incubation for 40 min., as can be seen in Fig. 1*a* and *b*.

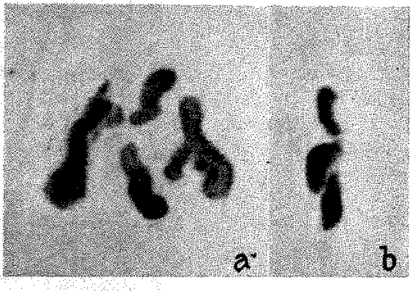

Fig. 1. Motor end-plate of the guinea pig's intercostal muscle: (*a*) in the plane of the section; (*b*) lateral view

An advantage of our method over frozen sections is that it allows sections to be cut as thin as $4-5\mu$ and to be handled on slides during the histochemical procedure; the reaction can be carried out even several days after embedding. Further, it permits the preparation of serial sections, some of which may then serve for other histochemical reactions or stainings. An inconvenience in using polyethylene-glycol as an embedding medium is the hygroscopic nature of the wax, which in the relative high vapour content and temperature of the surrounding air makes sectioning difficult. With time, the acetylcholinesterase activity gradually diminishes in the block. Several days after embedding it is still significant, and to obtain good results the incubation time should be increased by one-third to one-half. One month after embedding, the enzyme is difficult to demonstrate.

Changes in the Amount of Nucleic Acids and Free Nucleotides during Early Embryonic Development of Sea Urchins

During the early embryonic period, the embryo of the sea urchin[1,2], and also those of the frog[3] and the chicken[4], live upon deoxypentose nucleic acid, stored within the cytoplasm of the embryo; this reserve is used for the nuclei as they increase in number. Only after a certain period of development does the embryo start synthesizing deoxypentose nucleic acid itself. The time of appearance of this new synthesis is naturally different in animals belonging to different orders; but even within the same group of animals, closely related species start this synthesis at varied developmental stages. We have found this to be true for some species of sea urchins, *Paracentrotus lividus* from Roscoff, France, *Psammechinus miliaris* from Roscoff and from Kristineberg, Sweden, and *Echinus esculentus* from Kristineberg. The embryos of *Paracentrotus* and *Psammechinus* were reared at + 18° C. and those of *Echinus* at + 12° C. When cultivated at 12° C., *Paracentrotus* and *Psammechinus* showed almost the same rate of development as *Echinus*.

For the estimation of the nucleic acids as well as for the free nucleotides a method was used[5] by which the homogenate is extracted with 10 per cent sodium chloride at + 85° C. Ribonucleic acid and deoxypentose nucleic acid were precipitated by ethanol. The nucleotides in the supernatant were precipitated by lanthanum acetate. Ribonucleic acid was separated from the deoxypentose nucleic acid by alkaline hydrolysis for 5 hr. The fractions were estimated spectrophotometrically in ultra-violet light. We have also compared this method to that of Ogur and Rosen[6] and found good agreement.

Fig. 1 represents typical series of measurements. On the average, five further series of determinations were carried out for each species, which all gave curves of identical shape. From the figure it is obvious that the three species investigated start the synthesis of deoxypentose nucleic acid at different stages: *Paracentrotus* at the 32-cell stage, *Psammechinus* at about a 100-cell stage and *Echinus* at about a 500-cell stage. The absolute amount of deoxypentose nucleic acid stored in the unfertilized egg may vary greatly within the same species. Thus we have found, for both *Paracentrotus* and *Psammechinus*, samples of eggs which contained only about one-tenth of the amount of stored deoxypentose nucleic acid indicated in Fig. 1, and in spite of this fact synthesis of the acid started always at the same stage and development led to normal plutei.

It seems as if during the earlier part of the breeding time the eggs contain more deoxypentose nucleic acid than in the later stages. Thus it is not the actual amount of stored deoxypentose nucleic acid in the single embryo which determines the moment at which the synthesis begins. However, on the average, the embryos of *Paracentrotus* contain the smallest amounts of stored deoxypentose nucleic acid and those of *Echinus* the highest. For *Paracentrotus* it has been shown earlier[7] that the synchronous cellular division which initiates embryonic development stops at exactly the same stage as the synthesis of new deoxypentose nucleic acid starts. This has now been demonstrated to be valid also for the two other species mentioned.

Testosterone propionate has been found to inhibit the formation of nuclear deoxypentose nucleic acid

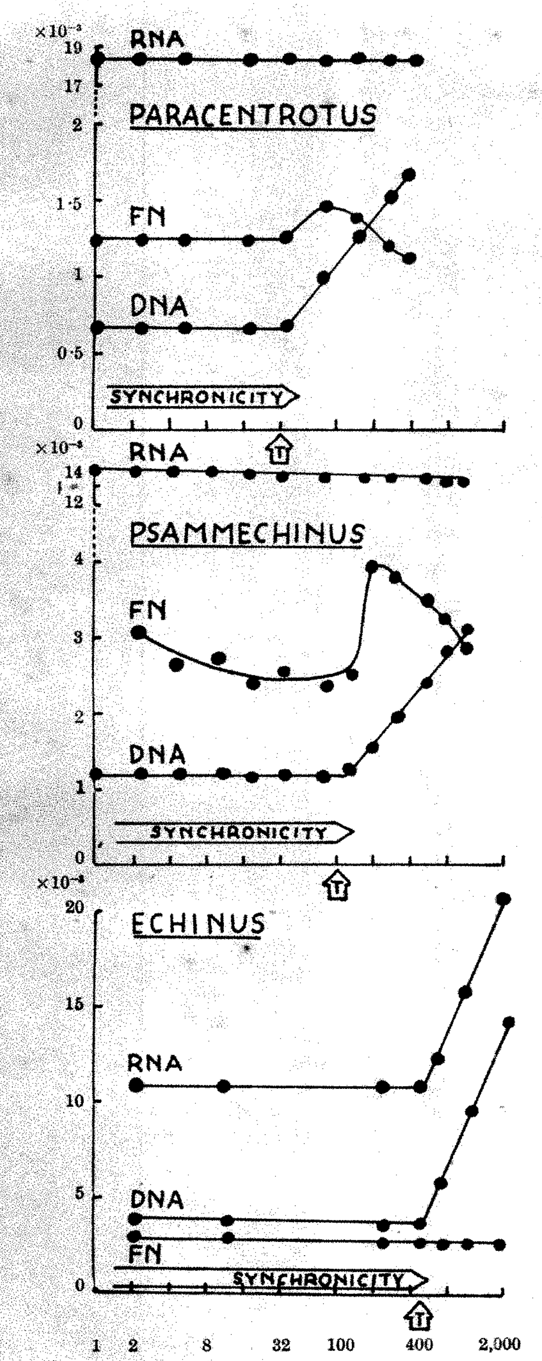

Fig. 1. Change in amount of deoxypentose ribonucleic acid (*DNA*), ribonucleic acid (*RNA*) and free nucleotides (*FN*) during the early embryonic development of three species of sea urchins. The period for the synchronous cellular division is indicated. The arrows marked *T* represent the moment when testosterone propionate added at the 2-cell stage inhibits cellular division and deoxypentose nucleic acid synthesis. Vertical axis: Amount of acid (γ) per embryo. Horizontal axis: embryonic stage expressed as the number of cells of the embryo

when its synthesis in *Psammechinus* begins[2] and correspondingly to block the cellular cleavage exactly when synthesis of the acid should start. Testosterone propionate has just the same action in the two other species. By the action of testosterone very broad chromosome bridges form at anaphase at the 16–32-cell stage in *Paracentrotus*. In *Psammechinus* these anaphase bridges form at the 128-cell stage and are long and slender. In *Echinus* the cells are just able to carry through the division at the 500-cell stage but die afterwards. Furthermore, it has been found that there is also a relation between the time when synthesis of deoxypentose nucleic acid starts and the time of hatching. The embryos of *Paracentrotus*, which start their synthesis of deoxypentose nucleic acid first, hatch as early as at about an 800-cell stage, *Psammechinus* at about a 1,000-cell stage and *Echinus* only after having divided to about 1,500 cells.

As regards the content of ribonucleic acid within the embryos, it is observed from the curves that during the embryonic development the ribonucleic acid remains constant for a long period. Only in *Echinus* is there a sudden new synthesis of ribonucleic acid, which occurs for some reason at the same time as the synthesis of deoxypentose nucleic acid. For the other two species the ribonucleic acid content has been followed beyond hatching without any sign of synthesis of new ribonucleic acid. It may be observed that for these two species the ratio of deoxypentose to ribonucleic acid is much higher than in *Echinus*. However, the course of the ribo- and deoxypentose nucleic acid curves for each species gives no support to any assumption of an inter-conversion of the two nucleic acids.

The amount of the free nucleotides is constant during the whole period investigated for *Echinus*, but shows a temporary increase around the time for deoxypentose nucleic acid synthesis in the other species. By paper chromatograms it has been found that new nucleotides form at this time, and we presume the visible change in the amount of the free nucleotides to reflect the turn-over rate of synthesis of deoxypentose nucleic acid. Thus, this synthesis may start with a synthesis of nucleotides, and not represent simply a process of polymerization.

Specificity of Gold Thioglucose for Ventromedial Hypothalamic Lesions and Hyperphagia

IN a recent publication[1] it was shown that gold thioglucose produces lesions in the ventromedial hypothalamic area of injected mice. It had previously been shown[2] that gold thiomalate, although similar to gold thioglucose with respect to toxicity, gold content and molecular weight, does not cause obesity; its injection does not lead to hypothalamic lesions[1]. To study further the specificity of gold thioglucose in causing ventromedial hypothalamic lesions and hyperphagia the action of other gold thio compounds was examined, in particular a compound where the gold thio moiety is linked to a radical very similar to glucose, namely, gold thiosorbitol (supplied through the kindness of Abbott and Co.), and compounds where the gold thio moiety is linked to metabolites other than glucose: besides gold thiomalate, gold thiocaproic acid and gold thioglycerol were available (also supplied by Abbott and Co.). The effects of gold thioglycoanilide and gold sodium thiosulphate were also examined. The main dose of each compound used in these experiments was calculated to provide as much gold as is contained in the dose of gold thioglucose found most effective to yield obese mice. (In a series of 800 Swiss mice treated with gold thioglucose 1 mgm./gm. body-weight was found to induce obesity in 60 per cent of surviving mice and varying degrees of ventromedial hypothalamic damage in all animals examined.) For each compound in addition to the main dose a number of multiples and fractions of this standard dose were used.

Nearly a thousand mice were used. None of the gold thio compounds other than gold thioglucose proved effective in inducing obesity, although the general toxicity of several of the doses used was of the same order as that of the effective dose of gold thioglucose. Finally, to test the generality of the action of gold thioglucose, the effect of its administration on the central nervous system of rats was examined. In the rat, gold thioglucose administration does not lead to obesity. However, rats appear to be more susceptible to the toxicity of gold compounds in general; the lethal effect of a dose of gold thioglucose effective in causing hypothalamic lesions might mask this latter effect. Accordingly, rats were injected with 1 mgm./gm. of gold thioglucose; control animals were injected with an equal dose of gold thiomalate. The animals were killed after 24–72 hr. Hypothalami of animals injected with gold thioglucose showed lesions consisting of diffuse hæmorrhagic areas and pyknosis and degeneration of nerve cells throughout areas of œdema and hæmorrhage. In all cases the ventromedial area was the area involved, with the ventromedial nuclei, arcuate nuclei and in some cases the supraoptic nuclei partly or wholly obliterated. The picture obtained was very similar to that previously described in detail for mice[1]. Gold thiomalate administration did not induce any visible hypothalamic damage.

The results presented herewith are consistent with the view[1] that the presence of the glucose component in the molecule makes the ventromedial hypothalamic barrier much more permeable to this compound than to compounds not containing glucose. This area has been shown through behavioural methods[3] to be a 'satiety' area inhibiting periodically a constantly activated feeding mechanism. The present findings support the idea that the ventromedial area exerts its influence on food intake behaviour because of its property as a 'glucoreceptive' centre in the sense postulated in the glucostatic theory of the regulation of food intake[4].

Metabolism of Lysergic Acid Diethylamide

IN a communication on lysergic acid diethylamide, Axelrod, Brady, Witkop and Evarts[1] state: "Although the hallucinogenic agent, lysergic acid diethylamide, has been the subject of numerous investigations, little is known about its biological fate". However, a number of facts, not mentioned in this communication, about the destruction, distribution and excretion of this compound have recently been published which show that we are not quite as ignorant about the biological fate of this compound as one might infer from this statement.

Lysergic acid diethylamide is neither bound nor destroyed in blood, because, when incubated with blood (rat) at 38° C. for 6 hr. and then assayed for its activity a 100 per cent recovery is obtained. The result is different when this diethylamide is added to homogenates of rat organs. In these, the activity of lysergic acid diethylamide decreases within a few minutes, but there is no, or only a little, further decrease in activity during the following hours and the same results are obtained whether incubation is at 38° C. or at 3° C. The activity of this diethylamide in the incubates has been assayed on the rat uterus by its inhibiting effect on the 5-hydroxytryptamine contraction. With liver and muscle homogenate the activity of the diethylamide became reduced within a few minutes to nearly 50 per cent; but scarcely any further reduction occurred during the next 17 hr. The lysergic acid diethylamide activity of brain homogenates was reduced to 42 per cent after 10 min., and to 21 per cent after 17 hr. These experiments do not differentiate between loss of activity due to binding of this diethylamide to some tissue constituent, and transformation into an inactive compound. The finding of identical results at 3° C. and 38° C., however, speaks against a metabolic transformation of lysergic acid diethylamide in the homogenates[2].

The distribution of lysergic acid diethylamide in blood and tissue at various times after its intravenous injection into mice or rats has been studied by either estimating the diethylamide biologically[2], or by injecting the diethylamide labelled with carbon-14 and determining it chemico-physically[3,4]. There was good general agreement between the results obtained with the two methods. The half-time value reached in blood was 7 min. in the experiments with the labelled diethylamide and 37 min. in those in which diethylamide was assayed biologically. Most of the organs reached the highest level of lysergic acid diethylamide after 10–15 min. and then lost it gradually in the course of the next few hours. The highest concentration was found in the liver after 30 min., when it was about six times greater than in the blood. The order of decreasing concentration of lysergic acid diethylamide in other organs was: kidney, adrenals, lung, spleen, pancreas, large intestine, heart, skeletal muscle, skin, brain. The concentration in the brain was at all times lower than in the blood.

In the experiments of Boyd *et al*[3] with labelled diethylamide, 7–8 per cent of the total activity was excreted within 12 hr., about half of this in the expired air, the rest in the urine and fæces, but 70 per cent was found in the intestinal contents. Stoll *et al.*[4] found 50 per cent of the injected dose in the intestinal contents within two hours after the injection.

There is no doubt that lysergic acid diethylamide or its metabolites are excreted in the bile. In experiments in which labelled diethylamide was injected into rats with bile fistulæ, Stoll *et al.* found that the bile contained within 2 hr. 70 per cent of the total radioactivity. The greater part of lysergic acid diethylamide undergoes chemical alteration because the excreted compounds or metabolites, in contrast to the diethylamide, were water-soluble. Paper chromatography revealed that the bile contained three radioactive compounds with the respective R_F values of 0, 0·13, 0·18. These compounds have not yet been identified chemically or biologically. The last two compounds give the Van Urk colour reaction and the blue fluorescence, characteristic for derivatives of lysergic acid, but neither of them is the 2-oxy-lysergic acid diethylamide, a compound obtained by Axelrod *et al.*, with *in vitro* "enzyme systems present in mammalian liver microsomes when supplemented with oxygen and a reduced triphosphopyridine nucleotide generating system". The problem of whether the third metabolite found in bile, which no longer gives the Van Urk colour reaction, is identical with 2-oxy-lysergic acid diethylamide has still to be examined.

Inhibition of Phosphoglucose Isomerase

The key carbohydrate intermediate, glucose 6-phosphate, which may follow several alternative metabolic pathways including the 6-phosphogluconate oxidative cycle and the glycolytic sequence, enters the latter route by the phosphoglucose isomerase reaction. This reaction, in which glucose 6-phosphate is reversibly converted into fructose 6-phosphate, could conceivably play a part in the regulation of carbohydrate metabolism, although it has seldom been considered from this point of view, doubtless because of the extremely high activity of the enzyme in most tissues and because the reaction has so far appeared to be very little affected by extraneous influences. The present evidence suggesting that the enzyme is strongly inhibited by 6-phosphogluconic acid, an intermediate in the direct oxidative pathway, may therefore be of interest in connexion with studies on the mechanism responsible for the partitioning of carbohydrate between the direct oxidative pathway and the glycolytic route.

The enzyme reactions were carried out by a technique similar to that described by Bodansky[1]. Crude phosphoglucose isomerase extracts from mammalian blood, liver and muscle were employed. Various preparations of 6-phosphogluconic acid made by the bromine oxidation of glucose 6-phosphate[2] were used. With glucose 6-phosphate at a concentration of 0·002 *M* as the substrate, inhibitions of the order of 95 per cent were observed in the presence of equimolecular concentrations of 6-phosphogluconic acid, and inhibitions of about 75 per cent were obtained using 0·001 *M* 6-phosphogluconate. A similar inhibitory effect was demonstrated using fructose 6-phosphate as substrate.

Separation of Neovitamin A_1 from All-Trans Vitamin A_1 by Chromatography on Alumina

In fish liver oils and synthetic preparations of vitamin A_1 it is possible to estimate the contents of the two isomers, neovitamin A_1 and all-trans vitamin A_1, by spectrophotometry following separation by chromatography on activated secondary calcium phosphate (dicalcium phosphate), length of column 300–600 mm. [1].

Even when the dicalcium phosphate has been subjected to the activation process previously described[1], the separation of the two vitamin A_1 isomers obtained is not equally satisfactory on all commercially available dicalcium phosphate preparations.

Earlier investigations have shown that a poor separation of the two vitamin A isomers is obtained by chromatography on columns consisting of the comparatively coarse-grained alumina which is usually marketed as suitable for chromatographic purposes. It has now been observed that good separation is obtained by chromatography on alumina prepared from fine-grained aluminium hydroxide.

The fractionation curve shown in Fig. 1 represents the results obtained by chromatographing 1·5 mgm. of a mixture of the alcohols of synthetic neovitamin A_1 and all-trans vitamin A_1. Chromatography was performed on a 75 cm. × 0·9 cm. column of aluminium oxide prepared as follows. Mixtures of diethyl ether and light petroleum with increasing contents of diethyl ether (2–25 per cent v/v) were used for the elution. Eluate was collected in 4-ml. fractions. On the basis of measurements of E_{325} for the individual fractions the ratio of the two vitamin A_1 isomers could be calculated. The result was: neovitamin : all-trans vitamin = 30 : 70.

The alumina used for the chromatography was prepared from aluminium hydroxide, analytical

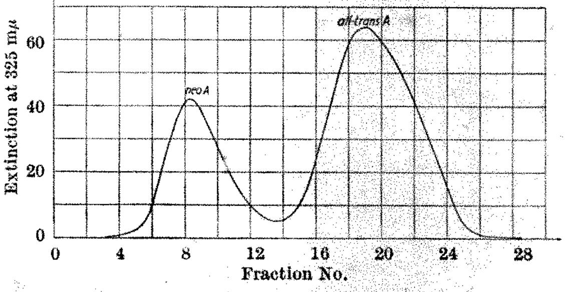

Fig. 1. Fractionation curve for synthetic neo- + all-trans-vitamin A_1 chromatographed on a 75 cm. × 0·9 cm. column of fine-grained alumina

grade ('Baker's analysed'), with a grain-size distribution characterized in that 100 per cent passes sieve *DIN* 80, while 97 per cent passes sieve *DIN* 100 and 70 per cent passes sieve *DIN* 150 *E*. A suspension of 10 gm. aluminium hydroxide in 40 ml. water has a *p*H of 9·6.

Aluminium hydroxide of this type is heated to 800° C. for seven hours[2] and cooled in an exhausted desiccator (a suspension of 10 gm. of this alumina in 40 ml. water has a *p*H of 10·2). Now 6·5 gm. distilled water is added to 100 gm. of alumina which has been transferred to a bottle with a close-fitting stopper. The bottle is shaken vigorously, and, when it has been allowed to stand for a couple of hours, the adsorbent is ready for use.

The rate of percolation through a 75 cm. × 0·9 cm. column of the prepared alumina was about 1·3 ml. per minute when applying a pressure of 0·4–0·5 atmosphere.

The losses involved in fractional chromatography were ascertained by comparison with the result of simple chromatography of 0·3 mgm. of the vitamin A_1 mixture used on a 10 cm. × 1·2 cm. column of dicalcium phosphate and simultaneous collection of the two vitamin A_2 isomers. The loss in this simple chromatography is 0·5–2 per cent[3]. The loss occurring in the fractional chromatography was about 10 per cent. In a similar fractional chromatography of 3 mgm. of vitamin A_1 on a 68 cm. × 0·9 cm. column of alumina the loss of vitamin A_1 was about 8 per cent.

Preparation and Properties of Dinitrophenyl-NH(ε)-Insulin

THE reaction of 2,4-dinitrobenzene sulphonate[1] with insulin has yielded a water-soluble and biologically active product. The only reactive group, which is shown to be substituted, is the ε-NH_2 of lysine in the hormone molecule.

30 mgm. of crystalline insulin (Eli Lilly) and 75 mgm. dinitrobenzene sulphonate were dissolved in 5 ml. 0·1 *M* sodium carbonate and was allowed to stand at 3° C. for 216 hr. The solution was then diluted to 25 ml. with distilled water, dialysed thoroughly in a cold room and lyophilized. The yellowish product weighed 30·5 mgm. The derivative (5 mgm.) was hydrolysed for 24 hr. at 110° C. with 0·5 ml. of constant-boiling point hydrochloric acid in a sealed evacuated tube. The whole hydrolysate was submitted to two-dimensional paper chromatography[2] to estimate quantitatively the amount of dinitrophenyl amino-acids. Only ε-dinitrophenyl-lysine in an amount of one mole per mole (6,000) of insulin was found to be present. The fact that the N-terminal glycine and phenylalanine in the hormone molecule are not substituted was further confirmed by the reaction of fluorodinitrobenzene[3] with the derivative. (Reactions of dinitrobenzene sulphonate with prolactin and ribonuclease also showed that terminal amino-groups are not dinitrophenylated.) Moreover, spectrophotometric analysis[4] of the derivative indicated that the tyrosine residue did not react with dinitrobenzene sulphonate under the experimental conditions. Since insulin contains only one lysine residue[5], the acid hydrolysate of the derivative gave no evidence for the presence of free lysine as analysed by two-dimensional paper chromatography in the solvent system previously described[6]. Thus, the derivative is dinitrophenyl-NH(ε)-insulin.

Preliminary studies showed that the solubility behaviour of dinitrophenyl-NH(ε)-insulin is similar to that of the native hormone. Unlike the dinitrophenylated insulin obtained by the fluorodinitrobenzene procedure[3], dinitrophenyl-NH(ε)-insulin is highly soluble in neutral solutions. In *p*H 7·2 trihydroxymethylaminomethane buffer of 0·10 ionic strength at 1° C., the derivative migrated as a single peak in a Spinco electrophoresis-diffusion apparatus with an electrophoretic mobility of $-7{\cdot}5 \times 10^{-5}$ cm.^{2} per volt per sec. which, as is to be expected, is lower than the value ($-6{\cdot}4 \times 10^{-5}$) obtained with native insulin. Additional physicochemical and biological characterizations of dinitrophenyl-NH(ε)-insulin will be presented at a later date.

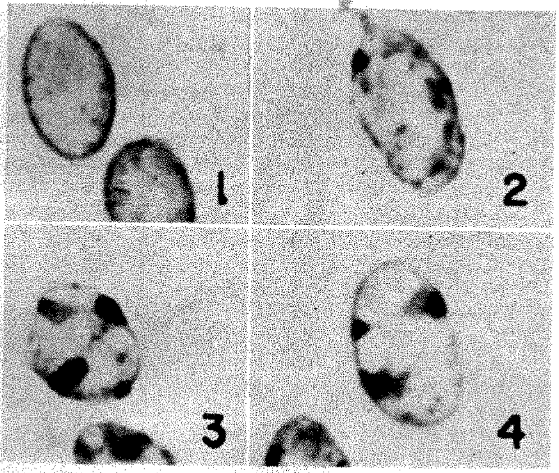
Possibility of Prenatal Diagnosis of Sex in Cattle and Sheep

WE have previously shown[1] that a correct prenatal diagnosis of sex can be made in humans by an analysis of cells from the amniotic fluid. This method of diagnosis, which has also recently been used in other laboratories[2], is based on a determination of the percentage of amniotic fluid cells with a chromocentre, especially a chromocentre at the nuclear membrane, a criterion that has also invariably given correct results when applied to human cells from other sources[3]. Since this method is so accurate in humans, we have examined the possibility of its application to cattle and sheep.

Our study in cattle has been based on epithelial tissues taken from young and old males and females after birth; from a 6-week, an 8-week and a 16-week-old male fœtus; and from a 12-week-old female fœtus. It was found that the cells in these tissues, most of which have several chromocentres, do not have the clear sex differences found in humans (Figs. 1–4). In a previous study on cattle a sex difference has been reported for nerve cells[4]; but such cells would not be found in the amniotic fluid.

An examination of epithelial cells from young and old male and female sheep after birth has shown that most cells have several chromocentres, and that also in this species there is not the clear sex difference found in humans.

Since no clear sex difference has been found in the nuclei of epithelial cells in cattle and sheep, a



Photomicrographs of cells from sections of skin. Feulgen and fast green staining. 1, human male, nucleus without a chromocentre; 2, human female, nucleus with a chromocentre at the nuclear membrane; 3, bull, nucleus with several chromocentres; 4, cow, nucleus with several chromocentres

prenatal diagnosis of sex based on the determination of the percentage of amniotic fluid cells with a chromocentre at the nuclear membrane cannot be made in these domestic animals.

γ-Amino-butyric Acid and Other Free Amino-acids in the Coconut

γ-AMINO-BUTYRIC acid has been described as present in the aqueous and alcoholic extracts of a number of plant and animal tissues[1-7]. In the course of studies on the nitrogenous constituents of coconut (*Cocos nucifera*) endosperm using paper chromatography, I have found this amino-acid to be present in amounts apparently larger than any other amino-acid except alanine in the watery liquid inside the mature fruit. Further investigations at three consecutive stages of development, namely, 4–5 months, 5–6 months and 6–7 months after setting of the fruit revealed that γ-amino-butyric acid is not present in the liquid endosperm at 4–5 months after setting of the fruit, but makes its appearance in the liquid when the solid endosperm has been deposited as a thin gelatinous layer on the nucellus in the fifth to sixth month after setting.

At this stage, γ-amino-butyric acid is barely detectable in two-dimensional chromatograms of concentrates of the fluid endosperm but is detectable in chromatograms of aqueous extracts of the solid endosperm. In the sixth to seventh month after setting when the solid endosperm has attained a thickness of about $\frac{1}{10}$ in., γ-amino-butyric acid can be clearly seen in both one- and two-dimensional chromatograms of concentrates of the liquid endosperm as well as in extracts of the solid endosperm. γ-Amino-butyric acid is not present among the products of hydrolysis of coconut globulin.

The γ-amino-butyric acid was identified in one-dimensional chromatograms by running an authentic sample of this amino-acid side by side with the solution being chromatographed; and in two-dimensional chromatograms both with and without addition of an authentic sample of γ-amino-butyric acid to the solution being chromatographed, as well as by the copper carbonate method of Crumpler and Dent[8].

The solutions used for chromatography were prepared by evaporating equal volumes of the endosperm liquid of fruits of different ages to small volume under reduced pressure and making up to equal volumes, the final concentration being 14–15 times. 2-ml. aliquots of these concentrates were passed through a 'Dowex 50' (15 cm. × 1 cm.) column, and after washing out the sugars with distilled water, the amino-acids were eluted with ammonia. The eluates were evaporated to dryness and the residues taken up in equal volumes of water. (Further elution of the columns with soda yielded only traces of ninhydrin-reacting substance.)

3–6-μl. aliquots of these solutions were used for one-dimensional chromatography and 6–12-μl. aliquots for two-dimensional chromatography. Phenol–water in the presence of 0·1 per cent ammonia and butanol/acetic acid/water (4 : 1 : 5) were used as solvents in the one-dimensional chromatograms which were run alongside a range of amino-acids, singly and in mixtures, on No. 1 Whatman filter paper; buffered (*p*H 9·3) *m*-cresol–phenol (1 : 1)[9] followed by butanol/acetic acid/water (4 : 1 : 5) using No. 3 *MM* paper gave the best results in two-dimensional chromatograms. After drying the papers in a current of air, they were sprayed with a 0·1 per cent solution of ninhydrin in butanol and heated for five minutes in an oven at 100° C. to develop the spots.

The following amino-acids were found at all stages of development studied: aspartic and glutamic acid, serine, alanine, valine, leucine and *iso*leucine. Threonine and glycine were present in much smaller amounts. Tyrosine, phenylalanine, tryptophan, α-amino-butyric acid and methionine could not be detected. In the case of the 6–7-month old fruit and the mature fruit, asparagine, glutamine, cystine, the basic amino-acids and β-alanine were found when larger aliquots of the liquid endosperm concentrates were used in two-dimensional chromatograms. Proline, in contrast to γ-amino-butyric acid, was present in largest concentration in the liquid endosperm of the immature fruit and decreased in amount with increasing maturity of the fruit until only a trace was present in the liquid endosperm of the fully mature fruit. Aspartic and glutamic acids increased somewhat and alanine and γ-amino-butyric acid increased markedly with increasing age of the fruit, while the others showed less marked variations. Concentrated aqueous extracts of the solid endosperm at 5–6 months and 6–7 months after setting and at maturity showed a distribution of amino-acids similar to that of the liquid endosperm at the 6–7 month stage. In addition, faint spots at positions corresponding to tryptophan, α-amino-butyric acid, tyrosine and phenylalanine were seen.

The appearance of γ-amino-butyric acid at the stage corresponding to deposition of the solid endosperm and its apparently increasing concentration in the liquid endosperm with increasing maturity of the nut suggest that this amino-acid arises as a result of some reaction connected with protein synthesis. A full account of this work will be published elsewhere.

I thank Dr. R. L. M. Synge and Prof. F. C. Steward for authentic samples of γ-amino-butyric acid; and Mr. B. P. M. Perera for technical assistance.

Selective Destruction of Mesenchyme in Tissue Culture by the α-Toxin of *Clostridium welchii* Type *A*

The α-toxin of the gas-gangrene organism *Clostridium welchii* type *A* is one of the few lethal toxins of known enzymic action; it is a lecithinase *C*, which splits lecithin into phosphoryl choline and a diglyceride[1]. It affects the enzymic activity of isolated mitochondria and lyses red blood cells[3]. Unfractionated *welchii* toxin caused histological changes in fragments of tissues and organs, including the release of fat globules, lysis of nuclei, and general break-up, that agreed more or less with the clinical picture[4], and destroyed guinea pig spleen in culture[5].

In the present experiments, explants, about 1 mm. across, of the organs of chick embryos (6–13 day) were exposed to various dilutions of the toxin for 30 min. at 38° C., washed, and grown in a clot of plasma and embryo extract as 'hanging-drop' cultures.

Untreated explants from most organs produced an outgrowth of fibroblasts and wandering cells. If the organ contained epithelium, whether and how soon the latter grew out depended partly on its relations to the surface of the explant; if any epithelium appeared in the zone of growth, it was usually overgrown in subculture by fibroblasts. It was found that in some concentrations the toxin would eliminate the fibroblasts and wandering cells from the outgrowth of many organs, including lung, mesonephros, metanephros, thyroid, pancreas, and gut, and leave the epithelium flourishing. Stained sections of rather larger explants that had been grown by the watch-glass method showed that the internal mesenchyme had been killed. The results with lung were especially striking, for after the connective-tissue stroma had been destroyed, the unfettered bronchial system was able to unfold. In the absence of connective tissue, the epithelial cells became disarranged, and after two days the tubules had given place to sheets, strands, and small vesicles. Cell division was very common, and subculture yielded pure epithelium.

The range of concentration over which the mesenchyme and the epithelium were killed varied from organ to organ. Thus, some of the mesenchyme of the metanephros was able to withstand exposure to 100 *LD*50 (mouse)/ml. (1 I.U. α-antitoxin neutralized about 25 *LD*50), whereas that of lung was completely destroyed at 10 *LD*50/ml. Much of the epithelium of the lung survived after the standard 30-min. treatment with 1,000 *LD*50/ml.; and that of the metanephros was still more resistant, some of it not being killed when grown in a medium that initially contained this concentration. In contrast, 10 *LD*50/ml. was lethal to both components of skin, though 1 *LD*50/ml. left them healthy.

Differential sensitivity was shown also by fœtal rat lung (17-day); a few fibroblasts grew out after exposure to 100 *LD*50/ml., but pure epithelial cultures were obtained after 1,000 *LD*50/ml.

The differential effect was still produced by the lecithinase after the traces of other toxins present had been inactivated by specific antisera.

This lecithinase may prove a useful tool for obtaining pure cultures of epithelium. The methods so far available for this purpose have depended on the selective inhibition of mesenchymal growth, except in those organs in which the two components are readily separable; whereas the lecithinase actually kills the mesenchyme selectively. For preparative work, a comparatively crude toxin would be adequate.

It is not yet clear how these results are related to those of Davidson and Waymouth[7], who found that the lecithinase *A* of snake venom changed the appearance of the cells in explant chick heart from elongated to polyhedral.

I should like to thank Dr. H. B. Fell and Dr. W. Jacobson for their most helpful interest in this work, Dr. M. G. Macfarlane for providing purified toxin, Miss M. Barr of the Wellcome Laboratories for antisera and a further supply of toxin, and Mr. A. J. May and Mr. W. J. Randles for their assistance.

Preservation of Corneal Endothelium by Freezing

The report[1] that spermatozoa from several species could be protected from the harmful effects of freezing by the addition of glycerol to the medium opened the way to the preservation for indefinite periods of a wide variety of mammalian tissues. An attempt to include the human cornea in this list[2] was only partially successful. It was suggested that the lack of complete success was due to the failure of the glycerol–saline technique to protect the corneal endothelium. It was therefore decided to investigate directly the effect of this treatment on the corneal endothelium of the rabbit.

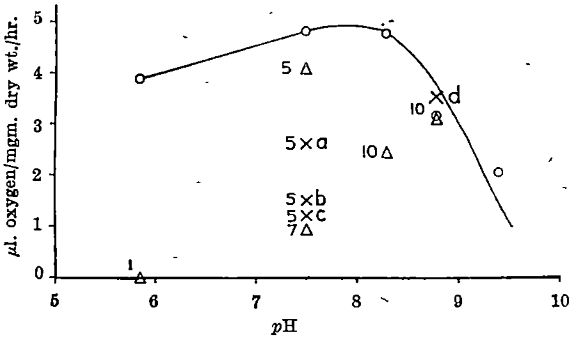

Fig. 1. The effect of pH, glycerol and freezing on the oxygen uptake of the corneal endothelium. ○, untreated corneæ; Δ, glycerol-treated corneæ; ×, glycerol-treated and frozen corneæ. The figure on the left of the symbol indicates the concentration of glycerol; the letter on the right the thawing procedure: *a*, thawed by immersion in water bath at 37° C. and maintained at that temperature for 60 min. before removal of endothelium; *b*, thawed at room temperature and allowed to stand 40 min. at room temperature before removal of endothelium; *c*, thawed by immersion in water bath at 37° C. (three minutes) followed by 20 min. at room temperature; *d*, thawed by immersion at 37° C. and maintained at that temperature for 20 min.

The criterion of viability employed was the oxygen uptake of the endothelium, and this was measured in a semi-microrespirometer designed specifically to respond to the small uptakes anticipated for a single endothelium. The whole, excised cornea was pretreated with the experimental solution and the endothelium, a monocellular layer, was removed along with Descemet's membrane; the tissue weighed about 1·3 mgm. when dry.

Eastcott *et al.* treated their material with 15 per cent glycerol in saline for one hour before freezing. In a preliminary series of experiments it was shown that such a long period was unnecessary, possibly harmful, and that 30 min. was sufficient to allow the cornea to come to equilibrium with the solution bathing it.

The results of the main series of experiments are summarized in Fig. 1. In physiological saline (pH 5·85) it is seen that even 1 per cent glycerol is toxic but that the resistance to the toxicity of glycerol increases with pH. It is also seen that at pH 7·5 and a glycerol concentration of 5 per cent, up to about 50 per cent of the cells can be made to survive freezing at −79° C. At pH 8·8 the endothelium is completely resistant to the toxic action of 10 per cent glycerol and at this glycerol concentration and pH the endothelium is completely protected against the harmful effects of freezing and thawing.

With the exception of the physiological saline all solutions were buffered and contained sodium chloride, potassium chloride, magnesium sulphate, and glucose.

Corneal grafting experiments in rabbits are in progress employing tissue frozen at −79° C. after treatment with 10 per cent glycerol at pH 8·8. Full details of all this work will be published in due course.

Effect of Testosterone and Androstene 3β-17α-Diol on the Activity of the Reticulo-endothelial System

It is now well recognized that the reticulo-endothelial system plays an important part in the defence of the body against infection. The cells act as scavengers in the later stages of acute infection, they function prominently in chronic infection and there is much circumstantial evidence to show that they play an important part in the production of antibodies. Nicol, Helmy and Abou-Zikry[1] found that the phagocytic activity of the reticulo-endothelial system could be increased by the administration of œstrogens. Unfortunately these substances have many unpleasant side-effects which restrict their use clinically. The influence of other steroids on the reticulo-endothelial system is therefore being investigated; the effects of cortisone[2] and deoxycorticosterone[3] have previously been reported.

The present communication deals with the effects of testosterone and androstene 3β-17α-diol. Forty-nine male guinea pigs were used. The reticulo-endothelial macrophages were studied by giving all the animals one daily injection of trypan blue subcutaneously for the last six days prior to being killed by chloroform. The dosage of the dye was calculated on the basis of 0·8 ml. of a 1 per cent solution in distilled water per 100 gm. body-weight. Seven of the animals were given dye only and were used as controls. The hormone treatment given to the remaining forty-two animals is shown in Table 1. Specimens were taken from the spleen, liver and lymph nodes and fixed in Heidenhain's 'Susa' fluid. Sections were cut at 10μ thick and stained with weak eosin, dilute carbol fuchsin or alum carmine. The activity of the reticulo-endothelial system in the organs studied was assessed by the number of dye-bearing cells and the intensity of the vital staining.

Table 1. HORMONE TREATMENT GIVEN TO FORTY-TWO ANIMALS

Number of animals	Hormone used	Daily dose intramuscularly	Duration of treatment
6	Testosterone propionate (Organon)	1 mgm.	1 week
6	,,	5 ,,	1 ,,
3	,,	5 ,,	2 weeks
9	,,	5 ,,	3 ,,
6	,,	5 ,,	4 ,,
6	Androstene 3β-17α-diol (Organon) dissolved in olive oil	1 ,,	1 week
6	,, ,,	1 ,,	3 weeks

The results were as follows:

Testosterone. In the group of animals which received 1 mgm. of testosterone daily for one week the intensity of the vital staining was slightly reduced in the macrophages of the spleen, but the appearances in the liver and lymph nodes remained similar to those of the controls. In those which received 5 mgm. daily for one and two weeks the intensity of the vital staining in the macrophages was slightly reduced after one week of treatment and markedly reduced after two weeks, the greatest reduction being seen in the macrophages of the spleen and liver. In the animals which received 5 mgm. daily for three or four weeks the phagocytic activity of the macrophages gradually returned to normal, and in those which received the hormone for four weeks the vital staining appearances were similar to those of the controls.

Androstene 3β-17α-*diol*. The animals which received 1 mgm. of androstene 3β-17α-diol once daily for one week showed vital staining appearances similar to those of the controls. In those which received 1 mgm. daily for three weeks there was marked reduction in the number of vitally stained macrophages and also in the intensity of the vital staining in the spleen, liver and lymph nodes.

The above results indicate that in the male guinea pig testosterone propionate depresses the phagocytic activity of the reticulo-endothelial system during the first two weeks of treatment; but if the injections are continued the system gradually recovers during the third and fourth weeks. The effect of testosterone is, therefore, similar to that of cortisone. Androstene 3β-17α-diol is also shown to have a depressant action on the activity of the reticulo-endothelial system.

For this research we gratefully acknowledge the gift of androstene 3β-17α-diol from Dr. Tindall, of Organon Laboratories, Ltd.

Agar Clarification

THE clarification of agar has always presented technical difficulties. The problem has become even more acute with the application of agar gels as a supporting medium for the interaction of antigen–antibody systems. A clear, transparent gel is essential for reading and photographing the lines, often fine and faint, formed by the antigen–antibody precipitates. That the classical microbiological methods of clarification, for example, filtration through sand and paper pulp, egg albumin coagulation, are insufficient is obvious from the elaborate, laborious methods devised in attempts to produce clear agar[1,2].

A very simple procedure for satisfactory agar clarification is here described. It is an adaptation of a step used by Viswanatha and Liener in the purification of a proteinase[3].

1 per cent w/v New Zealand agar is suspended in distilled water and dissolved by heating in a boiling water-bath. The solution is twice filtered rapidly through well-rinsed glass wool in a Buchner funnel to remove grossly insoluble particles. At this stage in our laboratory we add 1 per cent w/v sodium azide as a preservative, but this step is optional.

To the glass wool-filtered agar is added 1 or 2 per cent w/v of a mixture of equal parts of powdered bentonite and 'Hyflo Super-Cel' (Johns-Manville Co., Ltd.) and the whole shaken vigorously by hand to disperse the clarifying agents. The suspension is stored at 56° C. for several days, the clarifying agents being resuspended daily by gentle inversion of the bottles. When the cloudy flocculum is completely carried down from the supernatant by the bentonite–'Super-Cel' mixture the clarified agar is carefully decanted. Clarification is more quickly accomplished with 2 per cent of the mixture, but the recovery of agar is smaller.

The clarified agar is filtered through a fluted Whatman No. 5 paper in a heated funnel into a bottle standing in hot water. The first 25 ml. or so are returned to the funnel for re-filtering. The filtered agar in the molten state has the colourless clarity of water, and only a faint, clean, unclouded opalescence when set in plates.

Validity of Miley's Electrometric Method for the Qualitative Analysis of Oxidation Layers formed on Copper

IN a preliminary paper, published in 1951, L. de Brouckère, F. Bouillon and Y. Bouillon-Nyssen[1] showed that films formed on copper by anodic oxidation in molar solutions of sodium hydroxide contained, among other things, cupric hydroxide. This compound could be reduced electrochemically in $0 \cdot 2\,M$ solutions of ammonium chloride. The reduction potential was different from those of cuprous and cupric oxides, so that Miley's electrochemical method could, in principle, be applied to the qualitative analysis of mixed films. The various end-points were quite easy to localize.

The quantitative character of the electrochemical reduction of copper compounds in ammonium chloride solutions has been questioned by Campbell and Thomas[2], who suggested replacing it by potassium chloride, in which the copper oxides are completely insoluble. However, in this medium the potential-time curves are somewhat smoothed out, so that it is rather difficult to separate the various reactions occurring at the electrodes.

Ammonium chloride thus appeared to be the best electrolyte to use for qualitative analysis, potassium chloride being better suited for quantitative work.

Unfortunately, it has now been found that cupric hydroxide cannot be reduced in potassium chloride solutions, hydrogen being evolved from the very beginning of the electrolysis. A systematic study of these phenomena, which will be published shortly in the *Bulletin des Sociétés chimiques de Belgique*, has shown that copper hydroxide can only be reduced in such media as are able to dissolve it. Quantitative results can obviously only be obtained if the speed of reduction of the dissolved ions is greater than, or eventually equal to, the speed of dissolution.

We have been particularly interested in the reduction of copper compounds in solutions of sodium hydroxide as these have recently been used by several authors for analysing the films formed on copper by anodic oxidation[3]. Potential-time curves published in the literature generally have more than one horizontal part, and this has been interpreted as proving the complex nature of the films, which are supposed to consist of a mixture of cuprous and cupric oxides with some cupric hydroxide. We believe that this interpretation is not completely justified, especially

Table 1

Nature of the electrolyte used	General characteristics of potential-time curves		
	Films of 'pure' $Cu(OH)_2$	Films of 'pure' CuO	Films of dehydrated $Cu(OH)_2$
0·2 *M* KCl	No reduction	One long horizontal part (CuO) and one inflexion (Cu_2O)	One long horizontal part (CuO) and one inflexion (Cu_2O)
0·2 *M* NaOH	One long horizontal part and one inflexion	One long horizontal part and one inflexion	One long horizontal part and one inflexion
M NaOH	Three horizontal parts	One long horizontal part and one inflexion	One long horizontal part and one inflexion
4 *M* NaOH	Three horizontal parts	Three horizontal parts	Three horizontal parts

when strong sodium hydroxide solutions ($c \gg M$) are used.

The qualitative results presented here concern films made up of practically pure cupric oxide or hydroxide. Actually, as the primary product of anodic oxidation is always cuprous oxide, a small amount of this compound is probably present in every film; but it must be in very small quantity as it could not be detected in our X-ray patterns. Some of our results are summarized in Table 1.

Clearly, the number of kinks in the potential-time curve depends as much on the nature of the electrolyte used as on the composition of the layer analysed. In particular, complex curves can be obtained with films containing only one compound. Great care must therefore be taken in using Miley's method for qualitative purposes.

In a paper to be published later these results will be interpreted, and it will be shown that the total quantity of electricity used for reducing the film is proportional to the number of copper ions it contains. The method may therefore be used for quantitative measurements even when it fails for qualitative purposes.

This work was carried out under the direction of Prof. L. de Brouckère; we wish to thank her for help and criticism. We also thank the Union Minière du Haut Katanga for financial help.

Polarographic Determination of Rate of Periodate Oxidation of Epimeric Open-Chain 1,2-Glycols

The use of glycol-splitting reagents for the study of structural features in alicyclic glycols and sugars is firmly established[1], but only isolated instances of the application of this method to the study of epimeric pairs of open-chain vicinal diols are known[2].

A new and very advantageous method for following the glycol fission by periodic acid has now been developed, based on the polarographic determination of the reagent. This procedure, which is widely applicable, has several advantages over current methods. It is accurate, rapid, measurement is semi-automatic and the kinetic data are obtained in a single run without sampling; this is particularly striking in fast runs, where a recording of the complete kinetic curve is obtained (Fig. 1). Only milligram amounts of material are required for complete kinetic measurements, which, moreover, may be carried out at greater dilution (10^{-3}–10^{-5} *M*) than has hitherto been possible, and over a considerable range of *p*H. The accumulation and disappearance of the reaction product (aldehydes) may be followed in some instances, and any possible over-oxidation[3] (disappearance of iodic acid) is readily detected.

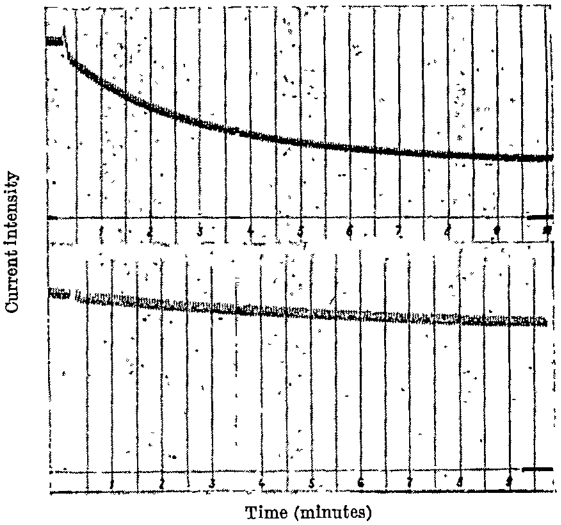

Fig. 1. Rate of oxidation of the threo- (upper curve) and erythro-1-phenyl-propane-1,2-diols in a 0·2 molar acetate-buffer of *p*H 4·7 with 1 molar sodium nitrate at 25° C., 6×10^{-5} molar glycol, $6 \times 10^{-5}M$ periodic acid. The change of the current registered with time at 0 V. (S.C.E.). The distance between abscissæ corresponds to 0·5 min., first abscissa in $t = 0·5$ min. Galvanometer sensitivity 2·2 $\times 10^{-9}$ amp./cm.

The method has already found very useful applications in the elucidation of the structure of natural compounds available only in semi-micro amounts; for example, in determining the structure of laserpitine[4] and in a study of steric problems in steroid 16,17-diols (Fajkoš, J., and Krupička, J., unpublished results).

Our principal aim in developing the method, however, has been the study of the oxidation of a series of stereoisomeric pairs of open-chain disecondary glycols. It was hoped that the rate data might yield useful information regarding the mechanism of this reaction on one hand and the effect of the steric bulk of the substituents on the other.

The applicability of the method was first verified by observing the reaction of ethylene glycol with periodic acid. The results were in satisfactory agreement with those recently obtained by Buist and Bunton[5], who regard the decomposition of a relatively stable intermediate as the rate-determining step.

In contrast to this, the oxidation of disecondary glycols has been found to follow simple second-order kinetics. The reaction is generally acid-base catalysed; general acid-base catalysis has been reported previously for the periodate oxidation of pinacol[6]. Rate constants of the acid- and base-catalysed reactions and of the uncatalysed reaction were determined

Table 1. Specific Second-order Rate-constants (l mol.$^{-1}$s.$^{-1}$ at 25° C.) for the Reaction of Open-chain 1,2-Glycols catalysed by Different Acids and Bases

$6 \times 10^{-5} M$ glycol, $6 \times 10^{-5} M$ potassium iodate

	Water	H_3O^+	CH_3COOH	CH_3COO^-	$H_2PO_4^-$	HPO_4^{2-}
1-Phenyl propane-1,2-diol: threo	9·2	1,360	Small	1,150	100	12,000
erythro	3·7	665	30	120	75	1,100
Butane-2,3-diol: threo	8 0	3,000	50	500	850	6,000
erythro	4 3	340	10	37·5	—	—

The values of k_{H_2O} and $k_{H_3O^+}$ have been determined in solutions containing nitric acid (pH 2–3) and 1 M sodium nitrate. To 0 2 M acetate and 0·07 M phosphate buffers, 1 M sodium nitrate was added

(Table 1). The base-catalysed reaction follows the Brønsted law. The value of the latter constant was found to be very close to the experimental values at pH 3, which are given in Table 2. From these findings it follows that the mechanism operative in the reactions studied differs from that found by Buist and Bunton[5] for ethylene glycol.

Consideration of the results presented in Tables 1 and 2 shows that the threo-epimers are in all instances oxidized faster than the erythro-isomers, the difference within the epimeric pair being more pronounced for the catalysed reaction than for the reaction in pure solvent. The difference in rates is sufficient to permit the analysis of mixtures of threo- and erythro-isomers and has, in fact, been successfully used for this purpose (Sicher, J., Šipoš, F., and Šorm, F., unpublished results. Šipoš, F., thesis, Institute of Chemistry, Prague). Furthermore, the reaction provides a simple and reliable method for determining the configuration of disecondary 1,2-glycols, provided both isomers are available. (The rate of reaction with glycol-splitting reagents has, of course, been frequently used for this purpose in the cyclohexane series. Recently, however, several instances have been reported in which the *trans*-isomer was oxidized faster than the *cis*[7].) On the other hand, the results show that the rate is not a simple function of the steric bulk of the substituents. Comparison of threo-isomers I, IX and IV, V points to an unexpected but marked accelerating effect due to the phenyl group; it should be noted that this effect does not occur with the corresponding erythro-isomer. The accelerating effect is apparently due to polar factors; it is, however, not enhanced by introducing the p-methoxy-group (VI). In the three purely aliphatic symmetrical glycols, k'_{threo} decreases with increasing size of $R = R'$, but again there is little variation in the corresponding value of k'_{erythro}. It should be noted that if the rate-determining step were the formation of a 'cyclic ester' or any geometrically equivalent species, it is the rate for the erythro-isomers which would be expected to vary with changes in R and R', rather than the rate for the threo-isomers.

Table 2. Second-order Rate-constants (l.mol.$^{-1}$s.$^{-1}$ at 25° C.) for the Reaction of Glycols with Periodic Acid

Values measured in 0·001 M nitric acid, 1 M sodium nitrate, $6 \times 10^{-5} M$ glycol, $6 \times 10^{-5} M$ potassium iodate (pH of the final solution adjusted to 3)

	R.CH(OH).CH(OH).R' R	R'	k'threo	k'erythro
I	Methyl	Methyl	9·9±0·1	4 8±0 2
II	Ethyl	Ethyl	8 8±0·1	4·4±0·2
III	Propyl	Propyl	5·5±0·1	4 9±0·1
IV	Cyclohexyl	Methyl	5·6±0·1	4 5±0·1

Structural Characterization of Cæsium Antimonide: Temperature Factors in Cubic Crystals

We have completed an X-ray investigation of cæsium–antimony alloys which shows that the photoelectric surface material cæsium antimonide is a 'normal valency' intermetallic compound with a small range of homogeneity probably from Cs_3Sb to $Cs_{3+x}Sb_{1-x}$, where x, estimated from the observed variation of unit-cell dimensions, is of the order of 0·05. The atomic arrangement is pseudo body-centred cubic with a structure based upon the $B32$ sodium thallide type (NaTl). The cubic unit cell (a = 9·14–9·19 A.) contains sixteen atoms at special positions of space group $Fd3m$—O_h^7. Eight equivalent sites at $(0,0,0;\ 0,\frac{1}{2},\frac{1}{2};\ \frac{1}{2},0,\frac{1}{2};\ \frac{1}{2},\frac{1}{2},0) + 0,0,0;\ \frac{1}{4},\frac{1}{4},\frac{1}{4}$ are occupied solely by cæsium atoms and eight other sites, at $(0,0,0;\ 0,\frac{1}{2},\frac{1}{2};\ \frac{1}{2},0,\frac{1}{2};\ \frac{1}{2},\frac{1}{2},0) + \frac{1}{2},\frac{1}{2},\frac{1}{2};\ \frac{3}{4},\frac{3}{4},\frac{3}{4}$, are occupied randomly by four cæsium and four antimony atoms. The structure may be described as consisting of two interpenetrating diamond-type lattices, one of cæsium atoms and the other of equal numbers of cæsium and antimony atoms. The semi-conducting properties of the material are explained by a filled Brillouin zone containing two electrons per atom. A full report of the investigation, together with a discussion of the cæsium antimonide structure and its correlation with other properties of the material, will be made elsewhere[1].

The observed X-ray diffraction effects from Cs_3Sb are accounted for only if the amplitudes of thermal vibrations are very much greater for cæsium atoms than for antimony atoms. In cæsium antimonide the root-mean-square displacements of the different atoms from their mean lattice positions (0·52 A. for cæsium and 0·25 A. for antimony at 291° K.) are approximately the same as the corresponding displacements in metallic cæsium and metallic antimony. This unexpectedly large difference between the Debye temperature factors of the different atoms (f_{Cs} = 55, f_{Sb} = 51 at $\theta = 0°$ for the electron distributions of the atoms at rest) causes the appearance of a complete series of X-ray superlattice reflexions, with *h*, *k* and *l* all odd, which were at first erroneously thought to be due to specific shifts of some or all of the atoms from the special positions. Although the assignment of separate temperature factors to different atoms is well known[2], the need for this has been recently emphasized by Lonsdale and Grenville-Wells[3]. In discussing the different Debye factors observed for different reflexions of α-brass[4], Lonsdale and Grenville-Wells point out that the Debye factor for reflexions from a cubic crystal is independent of crystallographic direction only if all the atoms have similar thermal motions. They demonstrate that unless the exponential constant B is the same for all atoms, then the ratio F^R/F^T (R = rest, T = given temperature) will vary from one reflexion to another. They state that "the ratio may sometimes be less than 1; that is, the structure factor may be greater at high temperature than at a low one and may change sign".

The diffraction effects which we have observed from cæsium antimonide illustrate the validity of this statement in a striking way. For example, the values of the ratio F^R/F^{291} for a number of Cs_3Sb reflexions are listed in Table 1.

Table 1. VALUES OF THE RATIO F^R/F^T (T=291° K.) FOR SOME Cs_3Sb X-RAY REFLEXIONS

θ	*hkl*	F^R/F^T
8·4	111	+2·75
13·8	220	+1·56
16·2	311	−1·02
19·7	400	+1·43
21·6	331	−0·49
42·4	800	+2·96
43·7	733	−0·21
72·5	880	+6·28
74·7	971	−0·24

At low Bragg angles the ratios for reflexions with *h*, *k* and *l* all odd are greater than 1 and may be positive or negative; at higher angles the ratios are negative and much less than 1. For reflexions with *h*, *k* and *l* all even the ratios are positive and greater than 1 but they show a wide range of values.

Use of Radioisotopes in the Study of Wool Growth and Fibre Composition

Bern *et al.*[1], and Ryder[2], carried out hair-growth experiments involving the injection of mice with cystine labelled with sulphur-35 followed by the detection of radioactivity in the hair follicle using the autoradiographic technique of Pelc[3]. The preliminary results of similar experiments carried out with mice and lambs are presented here.

The shortest time after injection at which Bern took samples was 1 hr. In the present study moderate activity was detected in the vibrissal follicles of a mouse killed 6 min. after an intraperitoneal injection of about 40 microcuries of labelled cystine. Accumulation in the follicle of sufficient activity to produce an autoradiograph would be expected to take a little time. But the radioactive compound can be regarded as entering the follicle almost immediately after injection, because there was already slight activity in the follicles of a mouse killed only 2 min. afterwards.

Although there has always been activity in the bulb, it has never given a dense autoradiograph; even 6 min. after injection the densest autoradiograph was at a level higher up the follicle than the bulb. This stretched from the neck of the bulb into the fibrillary zone of the fibre, that is, the zone which gives the strongest reaction for sulphydryl groups and immediately precedes the pre-keratinization zone in which the sulphydryl reaction is less[2]. In the present study no activity was detected in the pre-keratinization (keratogenous) zone until two hours after injection when radioactive sulphur seemed to be just beginning to extend into that zone.

The immediate appearance of activity at a level higher than the bulb is in accordance with the findings of Bern[1], and seems to support his suggestion that compounds containing sulphur enter the follicle above the bulb. It also seems to support the suggestion of Ryder[2,4] that substances needed in keratinization could enter from the blood-vessel network surrounding the follicle. In addition, the greater grain density at levels higher than the bulb might suggest that in fact more sulphur enters from the surrounding net than the papilla.

In the lamb (skin sample taken ½ hr. after injection) the difference between the density of the autoradiograph of the bulb and of the regions immediately above it was less marked than in the mouse. The autoradiographic preparations were stained with Bennett's[5] sulphydryl reagent before the application of film, and the increase in grain density at levels of the follicle higher than the bulb is associated with increase in the reaction for sulphydryl groups. This suggests that the sulphur enters the follicle in a compound (probably cysteine) containing sulphydryl groups. But it may be that sulphur enters only through the papilla and that the autoradiograph is merely indicating the region with most sulphur. In fact, the sulphur arrives there so quickly that the entry route is uncertain. The possibility of growth up to that level is ruled out, and the short distance to the region with the strongest autoradiograph from the surrounding vessel net makes it tempting to suggest diffusion through the follicle wall, although the fluid content of the lower cells of the fibre would help diffusion up the fibre from the papilla. So far only sulphur fixed in the tissue has been detected; possibly frozen-dried preparations would show the route of sulphur into the follicle.

In the lamb perhaps the most striking finding was the uniformity in the density of the autoradiograph of the orthocortex and paracortex, that is, the dye-accessible and non-dye-accessible halves of the cortex of the fully formed fibre[6]. Mercer *et al.*[7] gave figures which suggested that the paracortex contained as much as two-thirds of the total cystine of the fibre. If this were so, one would expect the grain density of the autoradiograph of the paracortex to be twice that of the orthocortex. Autoradiographic preparations of fibres cut at about the level of the skin surface have been stained to show the orthocortex, and grain counts have been made of the density of the autoradiograph over each half of the fibre. The grains in three squares over each half of the fibre were counted at a magnification of × 1,080, using a ½-mm. eyepiece graticule. A series of results is

Table 1. Autoradiographic Grain Density Counts

	Orthocortex (D.A.)	Paracortex (non-D A.)
Fibres in skin sample taken 48 hr. after injection	28	41
	22	26
	23	18
Fibres in skin sample taken 5 days after injection	44	42
	47	34
	51	53
	56	51
	52	47
	59	65

shown in Table 1; no significant difference was found between the grain densities of the two halves.

The results obtained using this method therefore suggest that the orthocortex and paracortex each contain similar amounts of cystine.

I am indebted to Dr. A. Robson and Dr. M. C. Corfield for many helpful discussions on the procedure used; and for preparing the solutions used in the experiments. I wish to thank Mr. G. R. Standley for technical assistance.

Intracrystalline Free Volumes in some Host Lattices

Various instances are known of continuous crystalline 'host' lattices within which 'guest' molecules may be trapped[1,2]. Organic lattices of this kind include the networks formed by hydrogen-bonded quinol molecules in the quinol clathrates; hydrogen-bonded urea and thio-urea networks in the urea and thio-urea adducts. Among inorganic lattices the best known are the crystalline zeolites, the most open of which, faujasite, easily occludes molecules as large as *iso*-octane; and two different kinds of hydrogen-bonded watter lattice, each with cavities able to encage diverse molecular species. It is of interest to compare aspects of the geometry of the free volumes of these host lattices, and to contract the free volumes of the organic and the inorganic lattices. It is also interesting to know the upper limit to the free volume in such continuous networks. Accordingly, the spatial properties of some cage and channel systems are summarized in Table 1. The term 'free', used above and in Table 1 in relation to channel and cage dimensions, means not occupied even by the periphery of any of the atoms forming the continuous network.

Quinol clathrates and water clathrates have free volumes in the form of separated cavities, the windows or apertures leading from one cage to another having very small free diameters. Urea and thio-urea adducts have free volumes in the form of continuous uniform capillaries, non-intersecting and all parallel to the hexagonal c-axis. The zeolites have free volumes in the form of cages joined by quite wide windows to each of several other cages, so that a continuous system of intersecting channels results[12], with free diameters varying periodically along their lengths. The zeolites of Table 1 differ from the other host lattices in being quite stable in absence of guest molecules, and in permitting migration of suitable small guest molecules from one cavity to another throughout the crystal.

Van der Waals[4] has pointed out that the atoms surrounding the cavity in the β-quinol-argon clathrate are located near the surface of a sphere of 7·9 A. diameter. On subtracting the equilibrium diameter 3·7 A. of an aromatic carbon atom one obtains a free diameter of 4·2 A. Subtracting the collision diameter of such an atom, 3·3 A., gives a diameter of 4·6 A. However, the β-quinol network is capable of some alteration according to the size of the included molecule. For the quinol-sulphur dioxide clathrate[3], the free diameter and volume may be found from the volume of sulphur dioxide, estimated as liquid, which is occluded per cm.^{3} of crystal (Table 1). In this network the free volume is comparatively small. The corresponding data for the urea-adducts have been calculated from the crystal structure given by Smith[5], and for thio-urea adducts from the corresponding work of Lenné[6]. By treating the channels in the host lattice as cylinders, and allowing 3·0 A. as the van der Waals diameter of nitrogen[13], one obtains the results given in Table 1. This time the free volumes are very substantial indeed.

The cage diameters of water clathrates of types 1 and 2 are taken from a paper by v. Stackelberg and Muller[7]. They are derived from the co-ordinates of the water molecules forming the wall of each cage, and the diameters of the water molecules. The latter were assumed equal to the distances between the centres of oxygen atoms of adjacent water molecules. Cage 1 is a pentagonal dodecahedron, cage 2 is a polyhedron with 14 pentagonal faces, and cage 3 a polyhedron with 16 pentagonal faces. The free volumes of Table 1 have been obtained taking the cubic unit cell edge of 12·0 A. for the type 1 and 17·3 A. for the type 2 water clathrate. In both these structures a large free volume exists, though

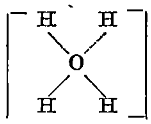
Table 1. Spatial Properties of Some Cage Systems

System	Free diameter of cage (A.)	Free diameter of apertures joining cages (A.)	Free volume enclosed by framework of host lattice (cm.^{3}/cm.^{3})
Quinol-SO$_2$ clathrate (ref. 3)	5·2	Small	0·09
Quinol-*A* clathrate (ref. 4)	4·2	,,	0·05
Urea-*n*-paraffin adducts (ref. 5)	5·2	5·2	0·37
Thiourea-hydrocarbon adducts (ref. 6)	$6{\cdot}1_3$	$6{\cdot}1_3$	0·41
Type 1 water clathrate (ref. 7)	Cage 1 5·2	Small	0·46
	,, 2 5·9	,,	
Type 2 water clathrate (ref. 7)	,, 1 4·8	,,	0·46
	,, 2 6·9	,,	
Chabazite (refs. 1, 8)	7·3	3·2 [4·9]	0·46
Zeolite 4*A* (refs. 1, 9)	Cage 1 ~7	~3·2 —	0·46
	,, 2 ~11·8	~4·4 —	
Faujasite (refs. 1, 9, 10)	,, 1 ~7	~3·2 —	0·53
	,, 2 ~12	~9 —	
Gmelinite (ref. 11)	~7·3	~3·2 [4·9]	0·46
Erionite	—	— —	0·44
Levynite	—	— [3·8]	0·40
Harmotome	—	— —	0·35
Mordenite	—	— [4·0]	0·33
Analcite	—	— —	0·20

both lattices are metastable with respect to ice or liquid water unless a substantial fraction of the cavities is filled by guest molecules.

For the zeolites chabazite, '4*A*', and faujasite, structural details essential from the present point of view have been presented elsewhere[1]. Chabazite, for example, is built by stacking slightly distorted cubo-octahedral cages in 8-fold co-ordination[8], and gmelinite also seems to be based upon the same framework[11]. The free diameter of the cages and the free volume within the crystals have been derived from unit cell dimensions and from the volume of zeolitic water which may be displaced from them. Molecules somewhat larger than the free diameters of the windows connecting adjacent cages can diffuse through these windows by an activated diffusion process, and I[2] have therefore also given in connexion with the molecular sieve property the larger dimensions in the square brackets of Table 1, column 3, based upon diffusion experiments. These, however, are not free diameters. Table 1 shows free volumes for some zeolites as large or larger than those found for the water clathrates. For six of the host lattices of Table 1 the free volume is 0·46 cm.^{3} per cm.^{3} or above, and the maximum figure is 0·53 cm.^{3} per cm.^{3}. It is possible, but not proved, that this latter figure is about as large as the free volume of a stable host lattice could be. However, this is not necessarily true of networks filled with guest molecules, but unstable in their absence.

The arrangement of 'bonds' around the oxygen atoms of water in the water clathrates is a slightly distorted tetrahedron,



so that these structures are in this respect analogous to the alumino-silicates (zeolites). It is these networks, based upon the tetrahedron, which so often show large free volumes. It may be inferred that tetrahedron-based network phosphates and borosilicates with large free volumes may be possible. Gallo-silicates, gallo-germanates and alumino-germanates showing this property have recently been synthesized in this laboratory[14]. The possibility of open-cage structures based on other ultimate building units, such as the octahedron, must, however, also be envisaged.

The Hydrogen-Bond Strength of Ice

Pauling[1] estimated the strength of the hydrogen bond in water by taking the heat of sublimation of ice and allowing a reasonably guessed value for the dispersion contribution to the bond, and arrived at a value of 4·5 kcal./N bonds, where N is Avogadro's number. Later, Grunberg and Nissan[2] calculated the dispersion contribution from surface tension data by assuming that the dispersion energy equalled the work of cohesion as defined by Harkins[3]. By taking the internal latent heat of vaporization of water plus the heat of fusion as equal to the internal heat of sublimation of ice and subtracting the work of cohesion, a value of 3·71 kcal./N was obtained. They also made a calculation from the dipole moment (taking certain evidence from viscosity data into account) and found a value of 3·23 kcal./N. Recently, I[4] formulated a relationship between the elastic constants of cellulose sheets and the strength of the hydrogen bond. The same relationship should apply to ice and therefore it should be possible to calculate the bond energy from the modulus of elasticity.

Consider a cube of ice in which the crystallites are randomly oriented and let a uniaxial tensile stress f act on two faces producing a small strain $\delta\sigma$. The energy per unit volume stored in the cube δU is the product $f\delta\sigma$, or taking infinitesimal quantities

$$f = \frac{\mathrm{d}U}{\mathrm{d}\sigma} \tag{1}$$

If the orientation of the crystallites, or hydrogen bond direction, is assumed random, then, to a first approximation, we can take $\frac{1}{3}$ of the total bonds available to be in the direction of strain. Thus the volume which a strained hydrogen bond occupies will be v_m, where

$$v_m = 3 \times 18/N\rho \sim 100\ \text{A.}^3 \tag{2}$$

where N is Avogadro's number and ρ the density of ice. While it is permissible to think of $\mathrm{d}U$ on a macroscopic scale as distributed uniformly in the volume of ice, on the molecular scale we imagine it localized in the O—H and O..H bonds. If r_1 and r_2 are the bond-lengths of the O—H and O..H links, and if the bond-strengths are k_1 and k_2 respectively, then a macroscopic strain of $\mathrm{d}\sigma$ will distribute itself among the two links according to

$$\mathrm{d}\sigma = \mathrm{d}\sigma_2\,(r_2/v_m{}^{1/3})\,[1 + (k_2/k_1)] \tag{3}$$

Therefore, $f = (\mathrm{d}U/\mathrm{d}\sigma)$

$$= (\mathrm{d}U/\mathrm{d}\sigma_2)/\{(r_2/v_m{}^{1/3})\,[1 + (k_2/k_1)]\} \tag{4}$$

Taking the Morse function for $U(\sigma_2)$ as was done for cellulose sheets, we obtain

$$f = 2(a_2)^2\left[\frac{v_m{}^{1/3}}{r_2(1 + (k_2/k_1))}\right]^2 U_0\sigma - \text{terms in higher powers of } \sigma \tag{5}$$

$$\text{So } E = \lim_{\sigma\to 0}\,(f/\sigma) = 2(a_2)^2\left[\frac{v_m{}^{1/3}}{r_2[1 + (k_2/k_1)]}\right]^2 U_0 \tag{6}$$

where a_2 is Morse constant, of order 2; U_0 is energy of dissociation of the hydrogen bond per unit volume of material $= J\Delta H/2{,}000\,v_m N$; and J is mechanical equivalent of heat.

It follows, then, that ΔH in kcal./N bonds is given by

$$\Delta H = Er_2^2\,[1 + (k_2/k_1)]^2\,v_m{}^{1/3}\,N/2{,}000\,a_2^2 J \tag{7}$$

Values for E reported in the literature for ice[5] are grouped around $1·05 \times 10^{11}$ within $\pm\,0·05 \times 10^{11}$. Substituting the values for the other parameters (that is, $r_2 = (2\cdot76 - 1\cdot07) \times 10^{-8}$; $k_2 : k_1 \sim 1 : 8$; $v_m = 10^{-22}$) gives $\Delta H = 3\cdot2$ kcal./N bonds against 3·2 from the dipole moment and 3·7 from thermodynamical data. It appears that a figure of 3·4 ± 0·2 kcal./N bonds is the most probable value of the hydrogen bond energy for ice and water.

A Solar Magnetograph

THE first test observations for the detection and measurement of both small magnetic fields and small Doppler effects on the Sun's surface have been carried out during recent months at the Cambridge Observatories with a photoelectric magnetometer newly built under a grant from the Department of Scientific and Industrial Research. This instrument is a modified version of one constructed by H. W. Babcock some time ago at the Mount Wilson and Palomar Observatories[1]. It is used in conjunction with the Cambridge solar spectrograph which has a large diffraction grating of excellent quality, ruled by H. W. Babcock[2] and working in the 5th order, where it reaches a measured resolving power of 600,000. The Zeeman effect in a suitable Fraunhofer line is analysed with the aid of an electro-optical retardation plate of ammonium di-hydrogen phosphate and a fixed 'Polaroid'. The retardation of the plate oscillates in sign at 400 c./s. due to the applied potential of 3·5 kV. r.m.s. A selected portion of each wing of the Fraunhofer line is imaged on the cathode of a corresponding photomultiplier (*E.M.I.* type 6094). The outputs from the two photomultipliers are fed into a difference amplifier, and the resulting signal after amplification by a selective frequency amplifier is applied to a phase-sensitive rectifier. Time constants up to 10 sec. are provided. The difference amplifier rejects elliptical polarization from the cœlostat mirrors, and, provided the examining slits are correctly placed, small Doppler shifts of the line are relatively unimportant.

Directly the instrument was brought into operation it revealed a wealth of magnetic structure on the Sun's surface, as was expected from observations already made in Pasadena[3]. One of the most striking phenomena is the presence of comparatively large fields not located on any surface feature visible in ordinary integrated light. These frequently occur at some distance from an apparently single sunspot, near where one would expect to find the following spot of an ordinary pair, and with the appropriate polarity with respect to the leading spot. The existence of such fields appeared probable in rare cases from work carried out long ago by G. E. Hale[4], but they are rather difficult to detect by purely photographic methods, as were, for example, tried by one of us[5] using a kind of blink method. With the present instrument they are detected with ease.

If the slit-length of the spectrograph is reduced to about 4 sec. of arc on the disk, very small areas with rather strong fields, up to about 100 gauss, can, under the present conditions of high solar activity, be found in large numbers along the main sunspot belts, even when in white light nothing but undisturbed photosphere can be seen on the surface. Some of these fields may occur over very tiny spots or over the well-known pores which appear among the photospheric granules. Small optically visible spots have developed in some of these patches one or two days after their discovery, suggesting, as has already been anticipated from theory, that a magnetic field is probably the precursor of a sunspot. The long-standing problem as to where the lines of force leaving the Sun's surface in a spotted area eventually return to the surface may be brought nearer solution by observations of this kind.

The fact that very small areas, apparently only a few square seconds of arc in extent, sometimes reveal relatively strong magnetic fields suggests that the magnetic structure of the Sun's surface may be appreciably finer than can be resolved by the instrument in its present form. It may well be that the dimensions of this fine structure will in future be found comparable in character with the Doppler fine structure recently discovered in Fraunhofer lines both here and elsewhere[6,7] by the use of large diffraction gratings of exceptionally high quality.

The sensitivity of the present instrument is sufficient to detect fields of the order of one gauss, but only with a relatively long slit, which results in highly localized and rather strong fields being smeared out into apparently larger and rather weak fields.

The instrument can be adapted to measure very small shifts of Fraunhofer lines down to quantities of the order of 1μ, equivalent to Doppler shifts of a small fraction of 1 km./sec. The limit so far has been set by the general rigidity of the spectrograph building and by the seeing conditions.

Photoelectric Polarimeter using the Faraday Effect

THE sugar industry is becoming increasingly interested in the possibility of replacing polarimeters of the visual type with photoelectric instruments. Of the various designs which have been suggested, a promising one is that in which the plane of polarization of the light emerging from the polarizer is made to oscillate through a suitable angle. When the analyser is perpendicular to the mean direction of the plane of polarization, the emergent light intensity, though it may be modulated at twice the frequency of oscillation, has a zero alternating component at the fundamental frequency. This condition is detected by means of a photocell and amplifier, the system thus combining the advantages of a.c. amplification and of the half-shadow principle used in visual polarimetry.

The various mechanical methods which have been suggested for producing the desired oscillation of the plane of polarization are not very suitable for a commercial instrument, and it is therefore rather surprising that the potentialities, in this connexion, of the magneto-optic or Faraday effect have been overlooked. The amplitude of oscillation which can be so obtained is rather small, but this is not necessarily a disadvantage, as the following argument shows.

If θ is the total angle through which the plane of polarization swings, then the sensitivity, that is, the rate of change of photocell output with angle of analyser, varies as $\sin \theta$ and is therefore greatest for $\theta = 90°$. The precision, however, when it is limited solely by shot noise in the photocurrent, is greatest for $\theta = 0$, since the root-mean-square shot noise varies as the square root of the mean photocell illumination, that is, as $\sin \theta/2$. Moreover, the accuracy, as distinct from the precision, is likely to be limited mainly by disturbances of the kind which appear as a modulation of the light intensity. In terms of angle, therefore, the resulting errors may be expected to vary as (mean light intensity) ÷ (sensitivity), that is, as $\tan \theta/2$. It follows that both precision and accuracy will improve progressively with decreasing θ until θ reaches a limiting value where the sensitivity is so small that extraneous disturbances (for example, dark-current or amplifier noise) begin to take effect.

Experiments indicate that, if a photomultiplier is used as the detector, this limiting value of θ is well within the capabilities of a Faraday cell of practical design. The following details of the construction and performance of an experimental instrument may serve to illustrate this conclusion.

The Faraday cell employed a lead–zinc borate glass (Chance *DEDF* No. 030,181, Verdet constant about 0·14 min./gilbert) in the form of a cylindrical rod 10 cm. long and 1 cm. diameter. The coil surrounding this was wound with 18 *SWG* enamelled copper wire on a Keramot former to these dimensions: int. diam. 1·4 cm.; ext. diam. 3·6 cm.; length 11·5 cm. The coil was supplied with 1 amp. of alternating current at 50 c./s. (sinusoidal waveform), which sufficed to swing the plane of polarization through an angle θ of 6° with a power dissipation of only 1 watt. The detection system comprised an 11-stage photomultiplier, a.c. amplifier, phase-sensitive rectifier and output meter.

The 'light-gathering power' of the optics, as determined by the size and separation of the stops, was if anything rather less than that of a typical visual polarimeter. The instrument was illuminated with 5461 A. light from a mercury lamp and monochromator; the effective light flux may be judged from the fact that, with analyser and polarizer *parallel*, the primary photocurrent was about 2×10^{-9} amp.

In these circumstances, the root-mean-square fluctuation in meter reading, for a bandwidth, as set by the overall response time, of 0·1 c./s., was equivalent to about 1 second of arc in the angular setting of the analyser, a value quite close to the shot-noise limit. The stability over a period of several minutes was of the same order. These results indicate a performance much superior to that of a visual polarimeter, and have encouraged us to proceed with the design of a similar instrument suitable for industrial use.

The work described above has been carried out as part of the research programme of the National Physical Laboratory, and this communication is published by permission of the Director of the Laboratory. Acknowledgments are due to Mr. S. P. Middleton for the design of the Faraday cell and assistance in the experimental work.

Population Growth

Dr. C. B. Goodhart's article, "World Population Growth and its Regulation by Natural Means"[1], performs a useful service in emphasizing that 'family size' may be a very poor indicator of the extent to which the descendants of a family will increase or decrease in number over a period of generations. This latter property might be termed 'net reproductive capacity'. As he points out, family size and net reproductive capacity might be positively correlated in some circumstances and negatively correlated in others.

However, if as Dr. Goodhart suggests the 'families of low fertility' may be replacing the more fertile lines during the present period of rapid population increase (because of a greater net reproductive capacity when disease is controlled, etc.), there is still a difficulty in accepting that as a result " . . . the mean fertility should fall and the population should taper off to a new position of equilibrium at a much higher level of numbers . . . ". This surely could only happen if there were some sharp curtailment of the superior net reproductive capacities of the 'less fertile' after they had succeeded in displacing the 'more fertile lines'. In other words, after the tortoise has beaten the hare, what reason have we to believe that he will stop running ?

More important, however, is a second point, which Dr. Goodhart has touched upon only briefly. We know almost nothing about the differentials in net reproductive capacity which may exist within a population. In spite of this, there is continued speculation concerning the possible effects of such differentials on the size and quality of future human populations. The time would seem to be ripe for a shift in emphasis from speculation to a serious consideration of the feasibility of observing the differentials themselves.

Limited surveys are probably inadequate for such a purpose, but there is an alternative approach. Essentially complete information of the kind required exists, although unfortunately not in a readily available form, in the routine registrations of marriages, births and deaths. These are sufficiently specific in their information content to identify parents and offspring unambiguously. Thus individual lines of descent could conceivably be followed over an indefinite number of generations. Of course, to reconstruct even a single family tree from such back records by a process of searching would be excessively laborious.

At first sight it is difficult to imagine any simple procedure for making use of this kind of record to derive the net reproductive capacities for lines of descent differing with respect to family size, or some other important attribute. However, it is altogether possible that current procedures for obtaining vital statistics from these registrations could be modified to permit the future extraction of appropriate family data for whole populations, and spanning an indefinite number of generations.

There is reason for believing that such modified handling procedures might perhaps prove quite simple in operation. Until recently, no serious thought had been directed to this end; but preliminary discussions in Canada, initiated for a rather different reason, suggest that some form of population accounting which takes cognizance of the family relationships from generation to generation may in fact be feasible. Without going into details, the essential feature lies in bringing together by means of a coding system (such as might be used with a punch-card medium) those records relating to the births, marriages and deaths of the offspring from a single pair of parents. There are a number of ways in which this can be accomplished. The product is in essence a family tree of the population, complete with the dates of all events, family sizes, causes of death, and, eventually, degree of consanguinity of the parents.

Most of the speculations regarding future populations imply that the problem is of practical importance. If so, is it not time that we started recording and handling our vital statistics to permit appropriate observations to be made on the differentials of reproduction, so that we shall not always be forced to draw conclusions about future populations from such meagre data? The possible negative correlation between family size and number of descendants which Dr. Goodhart postulates represents only one of the possible relevant kinds of observation.

[1] Goodhart, C. B., *Nature*, **178**, 561 (1956).

There is perhaps one way in which the tortoise might be expected to continue to slow down after he has beaten the hare.

The suggestion was that families (in the sense of 'lines of descent') of low average fertility might come to predominate in the population as a result of selection for success in life when indiscriminate mortality was low. This low average fertility is seen as being due to their having a high proportion of individuals who are subfecund, whether as a result of physiological sterility or because they are 'psychologically infecund' and disinclined to marry or have children. Such infecundity, whether physiological or psychological, is congenital and likely to be at least partly conditioned by inherited genetical factors, so that its already surprisingly high incidence in some communities must be the result of natural selection. It was suggested that this selection for relative infecundity (correlated with other inherited characteristics of high survival value) was likely to be extended in the future. If that does indeed happen, and the incidence of subfecundity is seriously increased, then the rate of population growth should continue to slow down for so long as the selection pressure is maintained; and that is not directly dependent upon the total numbers of the population, nor upon its average fertility.

Splitting of Genera

The recent passion for the progressive splitting up of genera has spread through most branches of zoology and latterly to botany as well. In fact, the present phase in taxonomy is to lump species and split genera, thus making genera on the whole as small as possible. In some groups (for example, Heteroptera, Cypraeidae, birds of paradise) this practice has reached absurd limits. The steady march of this practice goes almost unnoticed until large general or popular books are compiled where all recent work is uncritically assimilated regardless of quality. Two such Australian works on shells[1,2] and a recent book on birds[3] are illustrations. They admirably serve their purpose of presenting to the public excellent well-illustrated identification handbooks; but the nomenclature used is highly unstable, which is particularly undesirable in a book of wide public appeal.

The solution for this problem lies with the two International Commissions for Nomenclature. It is not, of course, denied that a very large number of genera remain to be described; but the burden of proving their complete distinctness rests with the describer. At present, names are very often proposed on flimsy grounds and the work of proving their validity or otherwise is handed down to future workers. For example, Steadman and Cotton[4] have summarized the 'accepted' classification of the Cypraeidae, and the genera and even subfamilies are separated on characters which are no higher than specific. New genera are established using merely the specific characters of the unique species included without any additional evidence. The result is that two species such as *Cypraea tigris* L. and *C. pantherina* Sol. are placed in different genera, whereas they are only just distinct species which actually hybridize.

Such absurdities should have no standing in nomenclature. I would propose that taxonomists consider a clause to be added to the international rules laying down that no generic name proposed after a certain date (possibly placed in the past) has any standing unless full reasons are given for its separation, not merely that it must be accompanied by a description. The interpretation of the term 'full reasons' is, of course, of paramount importance and varies from group to group. For example, no mollusc genus should be proposed without a comparison of its anatomy with allied genera. Each group has its accepted characters used for differentiation purposes and these should be used. If in a group the main classification depends on one character, then the description of a new genus should include full details of that character. I believe some such clause is needed to prevent certain branches of taxonomy developing into a farce. The mere extra labour involved in describing more than the macromorphology will prevent many of the offenders from too lightly proposing names.

FORTHCOMING EVENTS

Thursday, December 27

Royal Institution (at 21 Albemarle Street, London, W.1), at 3 p.m.—Dr. H. Baines: "Photography". (First of a course of six lectures adapted to a juvenile auditory. Further lectures on December 29, January 1, 3, 5 and 8.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade A, for General Chemistry, at Birkenhead Technical College—The Director of Education, Birkenhead Education Committee, 63 Hamilton Square, Birkenhead (December 28).

Head (honours graduate in chemistry, physics or metallurgy, with teaching, industrial and/or research experience, Corporate Member of a Professional Institution, and preferably experience of administration in a Senior Technical College) of the Department of Pure and Applied Science (Grade II), at Enfield Technical College, Queensway, Enfield, Middlesex—The Secretary to the Education Committee, Middlesex County Council, 10 Great George Street, Westminster, London, S.W.1, quoting Ref. F/CW/2 (December 29).

Physics Graduate in the Department of Radiotherapy, for duties which include physical investigations concerned with the clinical use of rotation therapy, multicurie cobalt units, low voltage X-rays and radioactive isotopes, and also some teaching of radiographer students—The Assistant Administrator, The Churchill Hospital, Headington, Oxford (December 29).

Assistant Lecturer or Lecturer (preferably with special qualifications and interests in mineralogy and petrology) in Geology—The Registrar, University College of North Staffordshire, Keele, Staffs (December 31).

Research Fellow (male graduate in some branch of physical science, with experience of observing, and preferably also of photographic work) to assist the Superintendent at the Norman Lockyer Observatory, near Sidmouth—The Secretary, The University, Exeter (December 31).

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester 13 (January 1).

Chemist (with a degree of a British university and/or Associate Member of the Royal Institute of Chemists) with the Basildon Development Corporation, Sewage Treatment Works, to make chemical analyses of sewage effluent, trade wastes, etc.—The General Manager, Basildon Development Corporation, Gifford House, Basildon, Essex (January 4).

Hospital Biochemist, Senior grade (with a university degree in science or equivalent qualification) in the routine Biochemical Section of the Department of Clinical Biochemistry—The Administrator, Radcliffe Infirmary, Oxford (January 4).

Research Fellow or Senior Research Fellow in Poultry Science in the Faculty of Rural Science—The Registrar, University of New England, Armidale, New South Wales, Australia (January 7).

Head (with an engineering degree, Corporate Member of a Professional Engineering Institution, experience in industry and preferably as head of a department or senior lecturer in a technical college) of the Department of Engineering, Singapore Polytechnic—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (January 15).

Lecturer (with a good honours degree, diploma in education, and suitable teaching experience) in Geography, in the Department of Teacher Training, Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C 1 (January 15).

Pharmacologist (with a university honours degree with physiology and biochemistry as major subjects, and research experience in pharmacology) at the Laboratories of the Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Parkville, Victoria, Australia, to undertake and expand investigations on the pharmacological and toxicological properties of substances extracted from Australian plants, with special reference to alkaloids—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 201/105 (January 19).

Drummond Fellows for Research in Nutrition—The Honorary Secretary, Drummond Trust, University College, Gower Street, London, W.C.1 (January 31).

Lecturer in Psychology at the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, January 31).

Assistants in Chemistry—The Secretary of University Court, The University, Glasgow (February 1).

Postgraduate Research Scholars for research in Chemistry, Household Science, Nutrition or Physics—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (March 1).

Assistant or Associate Professor (with graduate training in physics, and research and practical experience in the field) of Geophysics—Head, Department of Physics, University of British Columbia, Vancouver 8, B.C, Canada.

Isotope Assistant (with a first- or second-class honours degree in physics or physiology)—The House Governor, King's College Hospital, Denmark Hill, London, S.E.5.

Laboratory Technician (with G.C.E. science and mathematics, preferably at advanced level, or laboratory qualifications) in the Physiology Department to assist with research—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Laboratory Technologist (preferably A I.M.L.T., and at least two years experience in a medical or veterinary biochemistry laboratory) in the Nigerian Federal Government Department of Veterinary Research, to assist the Biochemist in investigation of normal and abnormal conditions in livestock—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.3/43811/NF.

Lecturer (with a good degree and preferably industrial experience) in Metallurgy—The Secretary, Royal College of Science and Technology, Glasgow.

Parapsychologists (preferably married couple under 30, with degrees in psychology or allied subjects), to assist with the work of the Institute—The Director, Institute for the Study of Mental Images, Church Crookham, Hants.

Physicists, Principal Scientific Officers to fill responsible positions in a group developing prototype military reactors, and Senior Scientific Officers/Scientific Officers to assist them—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref A.1255/34.

Research Officer (with at least a Bachelor's degree in physics or engineering physics, plus several years experience in the theory of wave propagation, seismology and acoustics) in the Division of Building Research, National Research Council of Canada, Ottawa, for duties which will include basic research in ground vibrations, their propagation and their effect on building structures; dealing with construction problems relating to ground vibrations; studying effects on building structures of earthquakes, blasting, pile-driving, etc., and developing suitable instruments for the above studies—The Employment Officer, National Research Council, Sussex Drive, Ottawa 2, Canada, quoting Br.169.

Scientific Officers (Chemists) in the Metropolitan Police Laboratory—The Secretary, Room 165(S), New Scotland Yard, London, S.W.1.

Senior Technician in the Zoology Department—The Secretary, Royal Holloway College, Englefield Green, Surrey.

Statistician (with a degree in statistics or mathematics, and preferably experience in industry), to act as chief assistant to the Head of the Statistics Department, which deals with a wide range of problems in fundamental and industrial research, calling for the use of varied statistical and mathematical techniques—The Secretary, The Hosiery and Allied Trades Research Association, 4 First Avenue, Sherwood Rise, Nottingham.

FREEDOM IN THE UNIVERSITIES

LIKE other forms of freedom, academic freedom in British universities is sometimes misunderstood and too often taken for granted. It is heartening, therefore, to see that such a widely experienced vice-chancellor as Sir Eric Ashby has devoted considerable thought to define the internal conditions under which universities in the British Commonwealth of Nations are able to determine their own policies and to manage their own affairs. His concern was to examine how university constitutions may be worked in order to allow academic men to exercise their many conceptions of academic freedom*.

No university constitution can guarantee academic freedom, and, as Sir Eric clearly shows, almost any constitution can be made to work so that freedom is preserved. Oxford and Cambridge are autonomous societies, governed by academic men and without lay control. Since 1889 the Scottish universities have been governed by Courts on which there is some lay representation, although responsibility for academic matters is delegated to the Senatus, which is composed predominantly of professors. The modern, or civic, universities are governed by Councils composed predominantly of laymen, with some academic representation, though certain powers are delegated to the board of professors, which is usually called the Senate. The universities and university colleges of the Commonwealth have constitutions which resemble those of the British civic universities.

This summary overlooks the substantial variations among constitutions of modern universities. Until 1942, for example, the chief academic board of the University of Sydney (the Professorial Board) could deal officially only with certain delegated responsibilities and with matters referred to it by the lay governing body (the Senate): it was on occasion prevented from expressing its views outside these limits. By contrast, the academic bodies of the Universities of Manchester, Bristol and Nottingham (among others) have, since their foundation, been empowered "to discuss and declare an opinion on any matter whatsoever relating to the University". Even in procedures relevant to the maintenance of academic freedom, no two universities in the British Commonwealth operate in the same way.

A catalogue of university constitutions does not of itself throw much light on the conditions for maintaining self-government. In all constitutions, except those of Oxford and Cambridge, ultimate sovereignty resides in a governing body of which the academic staff does not form a majority; and beneath the governing body there is a hierarchy of finance committees, senates, faculties and boards of studies. Yet in very few universities and colleges in the Commonwealth does the governing body deprive members of the academic staff of the privilege of determining their own policies and managing their own affairs. When their constitutions are worked wisely, universities of the Commonwealth are able to ensure that every permanent member of the academic staff has an opportunity to take part in the formulation of policy, fully as effective as the part taken by the academic body at Oxford or Cambridge. This is surely the freedom which should be most jealously guarded.

Despite their unpromising framework of government, modern universities are able to function virtually as self-governing societies because, in general, the constitutions function, in Sir Eric's words, as "inverted hierarchies". No matter whence they emanate, ideas are fed into the administrative machine at the level of a department or faculty board and seep gradually upward until they are eventually submitted to the predominantly lay Council for approval. By and large, the main direction of flow of new ideas and proposals is from below upwards, and not in the reverse direction.

If there is to be academic freedom, the academic staff in a university should have *de facto* control of the following functions: (1) the admission and examination of students; (2) the curricula for courses of study; (3) the appointment and tenure of office of academic staff; and (4) the allocation of income among the different categories of expenditure. In healthy universities it is found that the governing body delegates these functions—sometimes by tradition and sometimes by legislation—to the academic body; and in healthy universities the academic body ensures that this delegation is not merely to an oligarchy of professors but is well dispersed among the whole teaching staff. Where, for one reason or another, *de facto* control of these functions is withheld from the academic body, academic freedom is insecure.

If lay governing bodies were to intervene in the admission of students, for example, there would be justifiable resentment from the academic staff. It is rare in the British Commonwealth of Nations for a qualified student to be excluded from a university on grounds of race or colour or religious or political belief; for this reason developments in South Africa are regrettable and disturbing.

A more common weakness is for the university to lose its control over standards of admission by accepting automatically any student who has passed, at some prescribed level, examinations controlled by an outside body. Indirectly, too, the university loses some control over its own standards of admission when recalcitrant local education authorities like the West Riding of Yorkshire refuse to finance students who, despite their having been accepted by a university, do not possess qualifications which are satisfactory to the local education authority.

In any university which claims to manage its own affairs, members of the academic staff must have *de facto* control of academic appointments. This is recognized in most university constitutions, which give the governing body authority to appoint academic staff only "after considering a report from the Senate". The effect of the general practice is to put the real responsibility for filling academic posts on the shoulders of the academic staff.

---

* *Bulletin of the Committee on Science and Freedom*, No. 7 (G. Polanyi, Wilmslow Road, Manchester; December 1956).

The procedure is not without its dangers. The Councils of a few universities still require two or more nominations from the academic body, and reserve the right to select the successful candidate on their own initiative from among these two or three names; in making their selection, Councils have been known to show preference for candidates with local or regional connexions. This is detrimental to the well-being of any university, and should be strenuously resisted.

Security of tenure in academic posts is guaranteed because most universities do not give themselves the power to discharge academic men except for moral turpitude or incapacity to fulfil their contracts; even then it is a power very rarely exercised. On those rare occasions when disciplinary action is taken against an academic man, the wise vice-chancellor ensures that the investigation, the report and recommendation are made by a group of the man's academic colleagues, and not by the lay governing body. There is an admirable tradition in the British Commonwealth which permits academic men to hold political and religious opinions with impunity, however repugnant these opinions may be to the governing body, and (on occasion) however irresponsible and indiscreet some academic men may be in promulgating their views.

This, and much other evidence besides, leaves no doubt that self-government is as widespread and as effective and secure in modern British and Commonwealth universities as in our two ancient self-governing universities. The constitutional differences between the two kinds of universities and the fact that there is *de jure* lay control in one kind and not in the other do not greatly influence the ways in which universities manage their affairs. In all of them policy is in the hands of the academic staff; where this is not guaranteed by statute it is ensured by tradition.

Whatever else flows upwards in universities, however, money flows downwards. Considerably more than half the income of all British universities comes from the public purse. No degree of self-government within universities could avail to protect them against intervention from their paymasters if they cared to intervene. In fact, in the United Kingdom, the paymasters have never intervened and show no sign that they are likely to do so.

Here is the potential danger to academic freedom in universities. The academic staff may control admissions, examinations, courses of study, and appointments; yet a lay finance committee, under a lay honorary treasurer, might so recommend the allocation of funds as to encourage one faculty more than another, or one department more than another, without regard to the wishes of the academic body. The constitutions of modern universities provide no safeguard against this, and here a heavy responsibility falls on the vice-chancellor.

The long and noble heritage of academic freedom in Europe has been preserved by a technique for working almost any form of constitution. The technique is to secure government by consent and, after consultation, by ensuring that there is an upward and not a downward flow of business and policy-making. There is an important condition for its survival, namely, that the principle of upward flow shall apply throughout the whole hierarchy and not merely between the Council and Senate. Yet, as Sir Eric shows, "not all professors consult their lecturers as scrupulously as they themselves expect to be consulted by the lay governors before decisions are made. As faculty boards become larger, there is a temptation for an oligarchy of senior professors to take over the responsibilities of government on behalf of their more junior colleagues. That way danger lies, for any weakening of the principle of self-government within the academic body makes it harder to preserve self-government within the university as a whole, and correspondingly harder to maintain the autonomy of the university in the modern democratic State". Who wishes to be consulted must consult.

RAMSAY

A Life of Sir William Ramsay, K.C.B., F.R.S.

By Prof. Morris W. Travers, F.R.S. Pp. viii+308+9 plates. (London: Edward Arnold (Publishers), Ltd., 1956.) 50*s*. net.

THIS is a book which one cannot put down: it is even dangerous to pick it up of an evening, unless the next day is to be an 'off' day. As scientific drama it is enthralling; as scene and portrait painting, vivid; and yet as history, which is fully and cogently documented, it is thorough; while the scientific descriptions, as one would expect, are technically precise. In this volume, written by Prof. M. W. Travers between his eighty-first and eighty-third birthdays, with all the strength of style of a man in his prime, we find a remarkable combination of high literary merit, good history, and good science.

In his preface, the author mentions his source-material. In 1913, Ramsay himself, at Ostwald's request, wrote a short autobiographical sketch, which is chiefly interesting for Ramsay's views on the influence of his ancestry, parentage, education and early contacts on his life and work. In 1916, Ramsay died. In 1918, Tilden published his "Memoir" of Ramsay, in which he records much of what is known of Ramsay's childhood and youth. But his account of Ramsay's scientific work is uneven, and, as to his most important work, arid. The reason is that Tilden had no contemporary contact with it: he was never one of the "band of brothers", which Soddy found in London at University College, as he has described, when he came from Montreal to join Ramsay. Travers was one of that band: he and Ramsay together had discovered and isolated three of the five permanent rare gases. So Travers knew it all from the inside. In 1928 he had, with the aid of Ramsay's laboratory note-books, lent to him by Lady Ramsay, made a study of it in his "Discovery of the Rare Gases". Then, when Lady Ramsay died in 1937, she left a large collection of Ramsay's letters and other papers, which her daughter, Lady Tidy, presented as working material to Prof. Travers. These letters contained a wealth of illuminating information, some of it of first importance in relation to historical matters which had remained obscure or had actually become garbled for lack of precise information. Here was ample material for a new and authoritative biography. Prof. Travers spent the years 1937–39 and 1948–52 ordering this material, in combination with material which he had himself collected. The whole of this annotated source material, bound in twenty-four volumes, has since been presented by Lady Tidy and Prof. Travers to University College, and is now preserved in the library of the College. In 1952, Prof. Travers began writing the present book.

The book is fundamentally a critical as well as an informative contribution to scientific history. But Ramsay left so much on paper, as well as in survivors' memories, that revealed his personality, that the book is also a vividly graphic human biography. We see Ramsay making music, swimming and diving, sailing small boats, learning to paint, learning languages, making numerous friends, making journeys especially to see them, conversing with them, and writing them long and entertaining letters, his letters, like his conversation, full of wit, humour and generous feeling. We see him as a public figure, working unselfishly, often at tremendous pressure, for the organization of university education or of science; and we see him as "a fellow sticking in with tooth and nail to his work" in the laboratory—to quote a description he once gave of himself.

A reviewer must not spoil the story, but the reader of this book will discover how this man of many parts kept the University College of Bristol's head above water when it was almost drowning financially; how he took an initiative which led to the original establishment of government grants for British universities and university colleges; how he organized the first considerable importation of radium into Britain, at first for purely scientific purposes; how he then, with medical colleagues, founded radiotherapy; and how, with other colleagues, after sustained effort, he got it recognized in the University of London that the most fundamental university activity is research, and that teaching is barren without it. To this day, the University of London will dignify no one with the name of 'Teacher' who cannot show a considerable record of research publications.

So little support had research in universities in Ramsay's most productive period that he had to do consulting work, in order to earn the money to buy the materials to do it. These were the conditions in which he elucidated laws of liquid-vapour equilibria, partly with Sydney Young, discovered and isolated argon with Rayleigh, discovered and isolated terrestrial helium, discovered and isolated neon, krypton, and xenon with Travers, proved with Soddy the α-rays of radium to be charged helium, and measured the atomic weight of radon with Whytlaw-Gray, laying bare in this last work the pattern of radioactive change. Ramsay and Soddy bought their own radium with their savings or pocket-money. Travers got his compressor by reversing the valves of an old vacuum pump, and generated the hydrogen that he had to liquefy to attain the low temperature needed, from zinc and sulphuric acid in a beer barrel. Whytlaw-Gray's first 'research work' (he has told me this—it is not in the book) was to paint an old and rusty gasometer in an effort to make it gas-tight.

I personally would have liked the book to include some account of Ramsay's early views on the electronic theory of chemistry, which were ahead of their time; and I would have enjoyed a somewhat fuller account of the work with Whytlaw-Gray on radon, one of the finest examples of chemical manipulation of all time. However, Prof. Travers does go very fully and frankly into the one error by Ramsay, which has brought so much comfort to his detractors. In this again Ramsay was, in thought, far ahead of his time: he believed in the possibility of artificial transmutation—of 'atom splitting'—when no one else did, when to do so was heretical. He searched for it, and thought that he had found instances of its realization, in spectrum-analytical amounts; but actually impurities, in those amounts, had found their way, during his manipulations, into his apparatus. Ten years later, Rutherford really observed it, but only in one atom at a time. Three decades were to pass before it was effected on any analytical scale.

The book is illustrated, not only in the conventional manner of a scientific biography, with portraits, photographs of apparatus, and the like, but also with many photographic reproductions from hand-written letters by Ramsay, and to Ramsay, and from his laboratory note-books. Of course, the extracts thus reproduced are selected for their historical importance: they add greatly to the value of the book as history. But this sort of history is not dry or heavy with detail: days of joy are in store for all who read this permanently important contribution to chemical history.

C. K. INGOLD

SOCIAL CHANGE IN NEW GUINEA

New Lives for Old

Cultural Transformation—Manus, 1928–1953. By Margaret Mead. Pp. xxii + 548 + 16 plates. (London: Victor Gollancz, Ltd., 1956.) 25*s*. net.

DR. MARGARET MEAD returned in 1953, after an absence of twenty-five years, to Manus in the Admiralty Islands, the scene of her "Growing up in New Guinea". In the interval, the Manus had been occupied by the Japanese and liberated by the Americans, and had adopted, first a millenary cult which promised that a magical cargo of all kinds of trade goods would arrive if they threw all their old possessions into the sea, and then a rational modernization movement known as the 'New Way of Thinking'. This involved the union of thirty-three villages under a single elected council, the teaching of all boys to read, the establishment of a communal treasury from which, among other aims, alienated land would be brought back, the re-siting and re-building of villages and other public works by the labour of the whole population under the instructions of the elected leaders. Many of these activities were in line with the reconstruction policy of the Australian administration. The Manus were also bidden by their leaders to cease from the quarrelling which Dr. Mead had found so prevalent twenty-five years before, and not to support their kinsmen if quarrels did arise. She refers often to the 'code' of the New Way, and once to an offence under it, but she does not record it. Of the leader, Paliau, she says that his ideas as to method were vague, though he was certain that "the old bad culture was to be completely abandoned for a new culture which would bring the natives into world culture".

The lesson of Manus, in Dr. Mead's view, is that we need not be as apprehensive as some anthropologists have been of the disturbances that may be caused by radical social change. We should realize that the worst difficulties arise from the incomplete adjustments which Europeans force on subject peoples by 'selective giving'; both the phrase and the idea come from Malinowski, though the source is not acknowledged. Dr. Mead does, however, state the grounds for these apprehensions, and she makes quite clear the difference between the reasonable views which anthropologists have held and the absurd ones with which they have been credited. There cannot be many anthropologists now outside South Africa who believe that non-European peoples should be discouraged from adopting Western techniques and the social organization that goes with them. But Dr. Mead's own account suggests that the mere desire for change, even for total change, is not enough—that even if we no longer hesitate to promote change for fear of the problems that it will create, we must still realize that there will be problems. Some of us believe that the most useful application of the anthropologist's knowledge consists in pointing out these problems.

Not many British anthropologists would interpret the process of change as Dr. Mead does. For her, it occurs if a people's education has moulded their personality in such a way that they are capable of change, and if an example is offered to them which they consider worthy of imitation.

The entity which changes is a 'culture', a collection of ways of acting, feeling and thinking, and the change is a process of imitating the ways of others. In the case of the Manus, the example was the democratic way of life as embodied in the 'G.I.', who is friendly with his fellows instead of being surly and suspicious as adult Manus used to be. In Britain we do not see 'cultures' in confrontation, one 'accepting' or 'taking' items from the other as though they were displayed for sale, nor do we consider that society cannot change without changes in personality. To us a society is a body of people united by a system of recognized relationships within which they compete for such advantages as the system offers, including, of course, public esteem. The new situations that arise when a small-scale society is incorporated into a much wider economic and political system offer new opportunities, which again individuals exploit in so far as they expect to derive advantage from them. The difficulties of adjustment are difficulties of choice between alternative courses of action; the new activities may involve loss of esteem, the neglect of obligations, or conflict with vested interests; or the advantages of a change which is offered as an improvement may not be clear. A formidable difficulty in Dr. Mead's argument is that she tries at one and the same time to treat the events in Manus as the product of a unique combination of favourable circumstances and as a basis for generalization. Actually many simple societies have willingly accepted changes as radical as have the Manus, after an early period of conservatism such as the Manus also went through, but without their cataclysmic recent history. Not many of these, so far, have been in New Guinea. But the fact, which Dr. Mead insists upon so often, that New Guinea techniques are those of the Stone Age is not really very significant. The possession of iron tools does not imply a social organization so much nearer to that of the West as to make New Guinea unique.

Dr. Mead's writing is, in the main, refreshingly untechnical, though it is at the same time so sentimental that the straightforward physiological terms which she uses here and there produce a shock of incongruity. She seems to be cajoling an audience whose attention would not be held by a more matter-of-fact presentation, and this may cost her the interest of a harder-headed public. L. P. MAIR

MODERN PHYSICS FOR ENGINEERS

Modern Physics

A Textbook for Engineers. By Prof. Robert L. Sproull. Pp. xii+491. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1956.) 62s. net.

THE engineer who has a sound knowledge of wave propagation and communications theory, and is master of the associated mathematics, approaches modern quantum mechanics equipped with the basic concepts and vocabulary and much of the necessary technique. Prof. R. L. Sproull's excellent book is written for this type of reader, to supply a theoretical background leading to a proper understanding of physical processes of engineering importance. Electrical analogies for problems in other fields, such as optics and acoustics, arise naturally, of course; and, indeed, extracting the fullest significance from a differential equation by applying it generally ought probably not to be called analogy, unless we extend the term as far as wave mechanics itself. But the feature which makes the book so clear and interesting to read is the author's regular appeal to some macroscopic wave property of electromagnetic waves that is comparable with the behaviour of a wave-function; the theoretical physicist is shown, in fact, to be using the same methods as the practical man, though applying them to quite different problems.

Fundamental experiments on the particle and wave properties of the electron, proton and neutron are described in the earlier chapters and lead up to the idea of a particle guided by a wave-packet. The indeterminacy principle is shown to arise if we attempt to discern two co-ordinates of a wave-packet regarded as a modulated continuous wave, and the principle is discussed more fully with reference to pulse spectra in an appendix. Next, the Schrödinger wave equation is stated, and the meaning of the wave-function Ψ explained. The first step is to show that the equation does lead to some results when applied to simple problems: the case of a free electron in a square potential well, and then a bound electron. The rigorous analytical treatment is accompanied by a transmission-line analogy. Having, so to speak, established confidence in the method, the author applies it next to the Coulomb-field potential of the hydrogen atom, and shows that quantum numbers arise inevitably in the theory. 'Allowed' transitions with unsymmetrical integrals are likened to the radiating property of an antenna driven out of phase, and the transitions that are 'forbidden' because of symmetry to the non-radiating in-phase driven antenna. The exclusion principle, illustrated by the electronic structure of light atoms, is explained in more general form to prepare the reader for its use in solid-state theory.

A detailed quantitative discussion of ionic and covalent binding precedes the chapter on crystals and the metallic state. Lithium is taken as a typical metal, and the reason for its metallic properties deduced from its 2*s* wave-function. Next, a one-dimensional square-well model of a metal is considered, and compared with a wave-filter for which V is the analogue of Ψ. It is pointed out that matters are much more complicated with actual potential distributions in three dimensions (Brillouin zones are mentioned but not discussed) but that the general principles are the same. Three chapters on the mechanical, thermal and electrical properties of solids follow ; and these properties are explained in terms of quantum mechanics. Semiconductors and their many applications are treated fully, and the final chapters deal with thermionic emission, electron optics, radioactivity, and nuclear reactions.

The book is satisfying because the author does not attempt to oversimplify a difficult argument, but instead precedes it by taking simpler cases which allow of a naturally straightforward treatment and analysing them thoroughly. The mathematics is kept to a level that does not require the specialist techniques of the mathematical physicist. For example, the Fermi distribution is introduced with the statement that a Maxwell distribution for conduction electrons could not satisfy the exclusion principle, and this one does ; the formula for the Fermi distribution is stated without proof, but its meaning and some of its consequences are explained and worked out quantitatively in the fullest detail.

Many numerical exercises are included, and at the end of each chapter there are references to standard treatises ; the reader who has worked through this book should certainly be well equipped to consult such more specialized works with understanding.

G. R. NOAKES

DISEASES OF TOBACCO IN AFRICA

Tobacco Diseases, with special reference to Africa

By Dr. J. C. F. Hopkins. Pp. xvi+178+4 plates. (Kew : Commonwealth Mycological Institute, 1956.) 35*s*.

THIS book is one of a series published by the Commonwealth Agricultural Bureaux on diseases of tropical and subtropical plants. Dr. S. P. Wiltshire says in his foreword that it is designed for plant pathologists, extension officers and tobacco farmers.

The first part of the book is devoted to a detailed consideration of the problems involved in the production of disease-free tobacco seedlings and the maintenance of healthy plants from transplanting to reaping. The subjects discussed include the preparation of seed-beds, cleaning and disinfecting seed, spraying both in the seed-beds and in the field, and the effects of some cultural practices on disease control. The main points of all these operations are dealt with fairly comprehensively, though some of the recommendations will be questioned by the more progressive growers and by many of those engaged in tobacco research in Rhodesia to-day. Some examples of these might include the use of bricks and cheese cloth in seed-beds, the advice to remove and burn or compost all tobacco stalks in preference to ploughing them in, and priming (removal of lower leaves) as a method of disease control.

The second part of the book contains detailed descriptions of symptoms of diseases and disorders which may be encountered by tobacco growers. Following the pattern of his earlier handbook, "Diseases of Tobacco in Southern Rhodesia", the author introduces each description with a few notes on the causal organism. There are many excellent photographs and coloured plates showing symptoms of the diseases which are described in the text, and these should prove useful to students of tobacco culture, extension officers and farmers. The descriptions include some bacterial, fungal and virus diseases which are comparatively rare, as well as those which are more common. There are also sections dealing with physiological, deficiency and miscellaneous diseases and those peculiar to the curing barn.

Some of the control measures advocated do not find support in the data and recommendations published by the Tobacco Research Board of Rhodesia and Nyasaland in recent years. To that extent this book will tend to confuse rather than to clarify the thoughts of farmers on the control of diseases in tobacco. Nevertheless, this book brings together the author's experiences and personal observations of tobacco disease problems in the course of a long career in Africa, and will therefore be read with great interest by those working with this crop.

I. NEAS

BIOLOGY OF SENESCENCE

The Biology of Senescence

By Dr. Alex Comfort. Pp. xiii+257. (London : Routledge and Kegan Paul, Ltd., 1956.) 25*s*. net.

DR. COMFORT has made sure that there are no misconceptions about the subject of his book by calling it the "Biology of Senescence" rather than "The Biology of Ageing". He goes still further in precision by defining what he means by senescence. It is, he says, an increasing likelihood of death with increasing age, or "a decrease in viability and an increase in vulnerability". This precision has much to support it, and in fact one might say that the advance of gerontological studies is to some extent dependent upon the use of a scientifically accurate nomenclature. The word 'ageing', which is often used synonymously with 'senescence', has a very much wider connotation and could include all the changes in the individual following conception and until death.

In his book Dr. Comfort first provides an introduction and historical discussion. In this he devotes some space to that remarkable sponsor of the term 'biological time', Lecomte du Noüy, who in 1936 devoted a good deal of thought to a discussion of the significance of physiological and physical time : "Everything, therefore, occurs as if sidereal time flowed four times faster for a man of fifty than for a child of ten" and "a year . . . seems longer to a child" . . . . "Thus we find that when we take physiological time as a unit of comparison physical time no longer flows uniformly". Dr. Comfort takes a cue from these metaphysical circumlocutions and adds to this system "alcoholic time", which he defines as the apparent progress of a bottle towards emptiness as it appears to the alcoholic who drinks it. The author's final conclusion about Du Noüy's discussion of time is that he "has gone down clutching a platitude and come up embracing a metaphysical system". In other words, just as physiology suffered for hundreds or even thousands of years from the attempts by Pythagoras to apply the lore of number to it, so the study of senescence has long been bedevilled even to the point of "intellectual disaster" by this type of attempt to describe it in mathematical terms.

But it must not be thought that Dr. Comfort's book is all metaphysical discussion; far from it—there is (if one may be pardoned such a metaphor at this point) plenty of meat in it. There are sections on the nature and criteria of senescence, maximum longevities among various animals, the maximum life-span in man, the distribution of senescence among vertebrates and invertebrates, senescence in Protozoa, the influence of genetic constitution on senescence and longevity, growth and senescence and the mechanisms of senescence.

Dr. Comfort's book is the most comprehensive review on the subject of senescence that has appeared since 1920. The publishers' notice on the cover claims that it has been written to marshal information and suggest lines of investigation for the experimental attacks on old age. In my opinion it fulfils this aim, and it thus becomes an essential part of the bookshelf of anyone interested or working in the field of senescence—or even of 'ageing'. G. H. BOURNE

ENTROPIC ASPECTS OF INFORMATION THEORY

Science and Information Theory

By Prof. Leon Brillouin. Pp. xvii+320. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 6.80 dollars.

THE theory of information has not been long in gathering a motley crowd of associates. Too often, in consequence, it has found itself vaguely identified with a wide variety of studies, for which in fact it serves merely as a new and useful tool. "Science and Information Theory", by Prof. L. Brillouin, is a book calculated severely to redress the balance. For Brillouin, information theory means simply what might be called the statistical theory of 'unexpectedness', developed chiefly by Wiener and Shannon for the purposes of communication engineering.

The mathematical 'unexpectedness' or improbability of a signal, measured logarithmically, (log $1/p$), is directly related to the size of the most economical code-symbol to represent it. The average unexpectedness ($\Sigma p_i \log(1/p_i)$), over a long sequence of signals, indicates the minimum average number of code-symbols necessary for each signal-transmission. Extremely important and illuminating coding theorems follow from this quantification of 'unexpectedness' as the additive measure which has operational significance for the code-designer, and it is not surprising that it is termed the 'amount-of-information' in the signal.

Unfortunately, as Shannon has been quick to point out, the improbability of a message need have no direct connexion with its logical content—with the number and complexity of the statements it makes. His measure is not, therefore, as Brillouin (p. 1) would have it, a definition of *information*, but merely of the *unexpectedness* of information. As a mathematical index of unexpectedness it can be applied, of course, to other things than messages—to states of thermodynamic systems, for example, in which context the same average measure has long been known under the name of entropy. The entropy of an under-specified system is numerically proportional to the 'unexpectedness' of the information which a complete specification would provide.

It is this equivalence of entropy and 'amount of information' (in Shannon's sense) which Prof. Brillouin is chiefly concerned to trace in a wide variety of physical situations, including the mythical case of Maxwell's 'demon'. The treatment is lucid, rigorous and illuminating at many points; but the persistent confusion of the concept of information with the unexpectedness of information leads to unnecessary mystification at a number of points. A particularly unconvincing example is the discussion (p. 155) of "free information", as something held "in the mind" and so "not directly connected with any physical system". Metaphysics has its proper place; but this is metaphysics misplaced. The 'unexpectedness' which Shannon defined by $\Sigma p_i \log(1/p_i)$ is not (*contra* p. 10) an absolute quantity, but a function, defined only in relation to a chosen distribution of prior probabilities or 'ensemble' of events. In physics the distribution may be fixed by the temperature of the system; but in other contexts the probabilities may be determined quite otherwise, and the direct relation of Shannon's measure to physical entropy disappears. Much of the mystery can be removed if the reader will substitute 'unexpectedness' for 'information' wherever the Shannon measure is discussed, and define the relevant ensemble; but one is left with the feeling that many questions would have been differently expressed had the author done the same.

Having equated "Information Theory" with Shannon's theory of unexpectedness, Prof. Brillouin has to disclaim for it any interest in questions of the meaning and value of information. In point of fact, as the proceedings of three London symposia on this subject can illustrate, the general theory of information has a well-defined place for measures of *descriptive* information-content as well as of unexpectedness. The author does not appear to realize, for example, that the measure developed by Gabor, which he describes on p. 100, is precisely one of the measures of "structural information-content" (termed "logon-content" by Gabor) for which later (p. 291) he finds no place. To talk of "inconsistencies" (p. 291) between these complementary measures is simply to reveal misunderstanding of their nature.

As one might expect, the incidental expositions of fundamental physics throughout the book are masterly. It is gratifying, too, to find lucid accounts of work such as Mandelbrot's on word-statistics, and recent developments in the design of error-correcting codes, included among the more conventional topics. Schouten's name, on the other hand, is not mentioned, despite the similarities between some of his ideas and Brillouin's.

This is a stimulating work—sometimes to insight, occasionally to exasperation. A novice seeking to learn the gist and drift of information theory may find easier introductions elsewhere; but for the student who wants to broaden and deepen his thinking in Prof. Brillouin's chosen portions of the subject the book is to be recommended. D. M. MACKAY

The Draining of the Fens

By Prof. H. C. Darby. Second edition. (Cambridge Studies in Economic History.) Pp. xx+314+31 plates. (Cambridge: At the University Press, 1956.) 35s. net.

THE second edition of this well-known work follows sixteen years after the first. During that time much has happened in the Fens. The floods of 1947 and the threat of severe floods in them during the tidal surge of 1953 are in the memory of most of us. Prof. H. C. Darby does not, of course, write at great length on these matters, since they are but recent, even if particularly severe, episodes in a long line of floods and threats of floods in the past; but in his final chapter he brings his discussion of the draining up to date.

In other respects there are few alterations: minor errors are corrected, and the bibliography has been lengthened. It remains, as was recognized in 1940, a first-class account of one of the most interesting areas in Britain. Prof. Darby writes perhaps primarily from the point of view of the historical geographer, and the briefest glance at the book will show how very familiar he is with his authorities; but he has also made himself fully acquainted with the engineering problems which are so complex. I would have welcomed a rather more detailed discussion of his own views and those of Dr. H. Godwin on the lowering of the surface of the Fens, although there has been considerable modification made on pages 107–110 in the new edition.

The request to review this new edition was welcome in that it gave an added reason to re-read the book. It is, and will long remain, the standard work on the subject; and those who read it for the first time will not fail to be impressed by the extremely clear and scholarly way in which a highly complex subject is presented. It is a companion volume to the author's "The Medieval Fenland". J. A. STEERS

Structural Geology for Petroleum Geologists

By Prof. William L. Russell. Pp. x+427. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 56s. 6d.

THIS book is exactly what its title indicates. It is designed to guide the student and to refresh the memory of the established petroleum geologist. These are busy men absorbed in their business and have little time or inclination to read anything unessential. Structural geology, however, is essential to the finding and winning of oil, and Prof. W. L. Russell has succeeded in providing a useful and readable book. General theoretical discussion is limited, but many well-chosen examples of structure are provided as illustrations. The author remarks that "petroleum geologists at the present time rarely get training in surface field mapping after being employed", and this tendency to do more work inside and less outside seems to be true in much American experience. It means that what used to be common daily observation when petroleum geologists were field men is no longer so, and reading a book like this occasionally will serve to keep a trusty weapon sharp and bright.

A few bibliographical omissions have been noted. Hans Cloos is not mentioned in the account of structure models. J. W. Gregory does not appear in the historical reference to rifts. W. Q. Kennedy is left out of the list of literature on faults, although S. J. Shand's adverse comment on his work is quoted. M. I. Goldman's *magnum opus* on Cap Rock (*Geol. Soc. Amer., Mem.* 50) is absent, although some of his lesser earlier papers are mentioned. Fig. 5–21, p. 134, is a puzzle; but if it depicts a map of anything it is a horst and an anticline, not a graben and syncline. J. V. HARRISON

Mass-Transfer Operations

By Prof. Robert E. Treybal. (McGraw-Hill Series in Chemical Engineering.) Pp. ix+666. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 71s. 6d.

IN this book Prof. R. E. Treybal has summarized a vast amount of up-to-date and valuable information on the basic principles of diffusion and mass transfer, the operations depending on them, and their application to the design of plant. He divides these operations into gas–liquid, liquid–liquid, solid–fluid, and those with immiscible phases, and sub-divides them into humidification, gas absorption, distillation, liquid extraction, adsorption and ion exchange, drying, leaching, and "less conventional" operations such as dialysis and thermal diffusion.

The chapters on liquid extraction, adsorption and leaching are in many respects novel and deserve special commendation. Although the treatment is primarily theoretical the author has recognized the danger of a succession of formulæ becoming tedious (there are 144 under "distillation") and has broken up the text by introducing large numbers of excellent graphs and numerous "illustrations", that is, worked-out problems. There are also many clearly drawn diagrams showing the nature of the plant in which the operations under discussion are conducted. The whole makes a most informative and readable book.

One difficulty remains unsolved—the large number of symbols, still far from being standardized, necessary for the calculations. The author, in an endeavour to find a solution, has listed the notation for each chapter separately, but even this involves much turning over of pages during reading. With a new edition, which seems likely to be called for soon, the issue of a separate card with tables of symbols might well be considered. H. E. WATSON

Scientific and Learned Societies of Great Britain

A Handbook compiled from Official Sources. 58th edition. Pp. 211. (London: George Allen and Unwin, Ltd., 1956.) 35s. net.

THE second post-war edition of this compendious handbook, for which the British Council is now responsible, is on similar lines to the previous issues. Part 1 gives the names and addresses of research organizations administered by the Department of Scientific and Industrial Research, Medical Research Council, Agricultural Research Council and the industrial research associations, with a select bibliography on the organization of scientific research. It also lists the principal scientific and learned societies and institutes in Great Britain under sixteen headings according to their fields of activity, with details of their objects, membership, meetings and publications. Names of officials of these societies are given in some, but not in all, instances. The title pages of the various sections are not numbered, a practice which can be confusing in using a reference book.

An index of subjects and societies completes the volume, which forms a most valuable reference source of British scholarship.

THE KING PENGUIN OF SOUTH GEORGIA

By BERNARD STONEHOUSE

Falkland Islands Dependencies Scientific Bureau, London, and Edward Grey Institute of Field Ornithology, Oxford

BREEDING behaviour in king penguins (*Aptenodytes patagonica*) has previously been described only from casual field observations (summarized by Murphy[1] and others) and from records of captive birds[2]. Recent work on a subantarctic colony has shown that neither provides an accurate picture of the remarkable, possibly unique, breeding cycle followed by this species in natural conditions. From October 1953 until December 1954 a colony of five thousand breeding birds was studied in Ample Bay, Bay of Isles, on the north-east coast of South Georgia. Adults, juveniles[3] and chicks were banded for identification and daily observations were maintained throughout a complete breeding season.

Fig. 1 (*A–B*) shows the composition of a 'typical' king penguin cycle generalized from more than a hundred case-histories.

After a period of fattening at sea, usually lasting one or two weeks, the birds spend between four and five weeks ashore undergoing a pre-nuptial moult. They fast during the moulting period, with a fall in weight from 20 kgm. to about 10 kgm.

The moult is followed by a second fattening period at sea, which may take more than three weeks in early spring or less than two weeks later in summer when food is more plentiful. On their return the birds assemble in the breeding colony to begin courtship. At this stage males, weighing 15–17 kgm., are slightly larger and heavier than females; the sexes can usually be distinguished on sight.

Courtship normally occupies about three weeks, but may extend to five or six weeks. A site is selected in the colony (often near the site occupied by one or other partner in the previous season) and is defended against encroachment throughout the late courtship and incubation periods. A single large egg is laid and held between abdomen and feet; no nest is built.

The incubation period is constant at 54–55 days. The first watch of 12–15 days is taken by the male; later the parents incubate alternately in spells which decrease from 12 to 4 or 5 days as full term approaches.

Chicks are fed by their parents through the winter and well into the following spring, usually for a total of 10–13 months after hatching. Well-fed chicks tended by diligent parents are ready for the sea before poorly fed chicks; those which lose a parent during the year take longest to mature but succeed if their remaining parent feeds them competently. Normally, the chicks are abandoned by both parents at some time during the down moult. Within three weeks of delivering their last feed the parents themselves re-appear in pre-moult condition.

The breeding cycle of this species cannot therefore be completed within a year; it usually occupies 14–16 months and may extend over a year and a half. By comparison, the emperor penguin (*A. forsteri*) rears a single chick in 8–9 months, while gentoos (*Pygoscelis papua*) and adelies (*P. adeliae*), like most other species of penguin, rear two young in less than six months.

The king penguin may lay its eggs at any time from late November to mid-April, over a period of 5½ months of the year. A corresponding figure for the gentoo penguin in South Georgia is two months, for the antarctic species emperor and adelie less than a month. Fig. 2 shows the annual duration of activities associated with breeding as seen in the South Georgia colony. The table was compiled and extrapolated from a single year's records; although other observations from South Georgia fit well into the framework, none is sufficiently critical to show whether or not a typical year is represented.

Breeding begins annually in November; and two breeding categories may be distinguished.

Early breeders are those birds which did not breed at all, or bred but failed to rear a chick, in the previous season. Most stay away from the colony throughout winter, although some appear at intervals of 3–4 weeks and associate with successful breeders in the colony. Early breeders undergo their pre-nuptial moult in September and October (Fig. 1, *A*), re-appearing from November onward ready for courtship. In 1953 and 1954 the first eggs were laid on the same date, November 25; by contrast, neighbouring gentoo penguins began laying three weeks later in the second season than in the first. Early breeders reach their peak of laying by mid-December; most have begun incubating by the end of the year.

Late breeders are birds which bred successfully in the previous season. Having fed their chicks through winter and early spring, they moult from late November onward (Fig. 1, *B*) and the first begin courtship early in January. Late breeders reach their peak of laying by mid-February. Although large numbers of courting and incubating birds are present in the colony from November onward, the January influx of late breeders is clearly distinguishable. In 1954 late breeders were estimated to outnumber early breeders approximately in a 3 : 2 ratio. Birds breeding for the first time are believed to form an intermediate group, laying early in January; many pairs

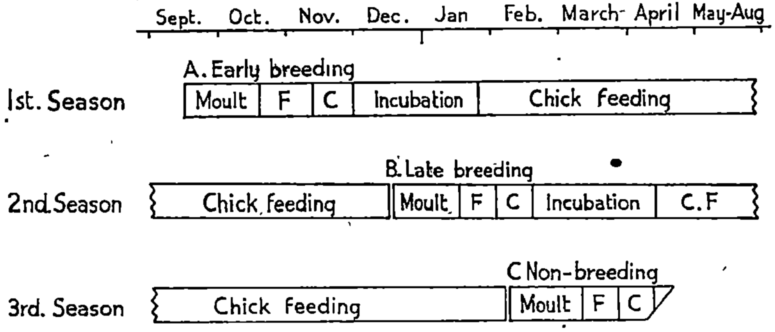

Fig. 1. A typical breeding history, showing the relation of breeding cycles to seasons

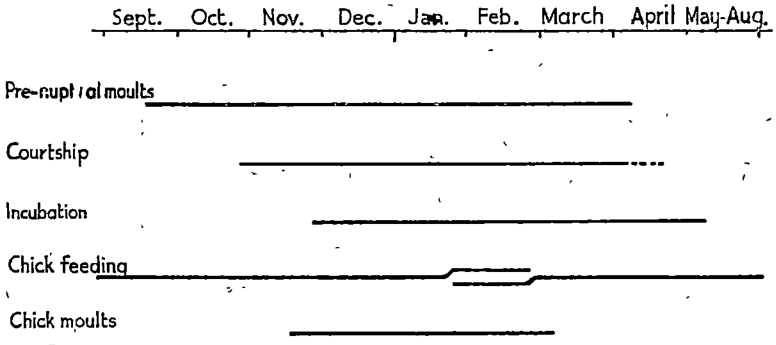

Fig. 2. Duration of breeding activities in all pairs

forming at this time showed indeterminate courtship patterns and inadequate care of their eggs.

Early breeders deprived of their egg lay again with the late breeders; of marked birds in this category more males than females were successful in rearing their chick after the removal or loss of a first egg. The last of the late breeders begin courtship in early April (Fig. 1, *C*); their courtship is desultory and incomplete, seldom resulting in a well-established bond. In May, when the first snow-drifts of the year begin to form, all the remaining eggs are abandoned. At the same time, all the chicks still held by parents are left to join crèches irrespective of their size; those less than a month old are not strong enough to fend for themselves and may die within a week. Only those approaching full size at this stage are likely to survive the winter. Thus, although late breeders may lay their eggs as late as mid-April, observations suggest that only those laying before the end of February succeed in raising chicks.

Fig. 3 shows the growth curve (weight/time) of a typical chick reared by an early breeder. Chicks are hatched with a covering of sparse down and are held closely on the parents' feet for the first week. They are fed every three or four hours by the nursing parent; parents change watch at intervals of 4–7 days. For the first 16–18 days the chicks increase in weight exponentially; later, their weights fluctuate more as large feeds are given less frequently. Chicks stay close to their parents for more than a month; at 5–6 weeks they wander and congregate in crèches which persist through the year from late February onward. The chicks at this stage are left by both parents, which return independently at intervals of about a week to feed them. Studies with banded birds showed that parents feed their own chicks exclusively, recognizing them primarily by sound and calling them out of the crèche with distinctive 'call-signs', to which only their own chick responds.

By late April chicks of early breeders are almost as big as their parents and weigh 11–13 kgm. Those hatched later may reach similar weights in May, but usually remain slightly lighter. Much of the weight is due to visceral and subcutaneous reserves of fat, which are gradually lost during the winter. From May onward feeding becomes irregular, presumably as a result of food shortage at sea, and well-attended chicks may be fed only at intervals of 5–6 weeks. About 2 kgm. of food (triturated cephalopod of unidentified species) are delivered in two or three successive morning feeds; for the next week the parent continues to feed the chicks on a small quantity of mucus (less than 100 gm. daily) secreted in the crop. After staying ashore for 10–15 days the parents return to sea, re-appearing only to bring the next meal. The chicks are by this time covered with down 4–6 cm. thick, and are generally well able to withstand the prevailing cold weather. Growth, as measured by linear increases of beak, foot and flipper, is retarded or stopped; the chicks lose weight at an average rate of 45 gm. daily between feeds, and from April until October there is an overall loss of about 5 kgm. per chick. Only those which reached an initial weight of at least 8 kgm. before May are likely to survive the winter.

In October the parents begin to visit more frequently, and by November are again feeding their chicks at least once weekly. The chicks increase rapidly in weight; by December those with both parents surviving have re-attained or exceeded their autumn weights. The second fattening period is associated with renewed growth and increasing calcification in the bones; the chicks are brought almost to full adult size, although growth is maintained throughout the juvenile (second) year. Juvenile plumage[4] appears under, and gradually replaces, the down. The first chicks enter the sea in December; moults continue through January and early February, but chicks still in down after mid-February are abandoned by their parents and probably are already dying of starvation. Healthy chicks whose parents are lost early in spring may moult successfully after starving for two or three months, and may enter the sea weighing 4–5 kgm., about half the normal weight for a well-fed chick at the end of its moult.

The parents abandon their chicks independently, usually within three weeks of each other, and undergo a prenuptial moult. In two recorded cases, one parent continued to feed the chick while the second completed its moult and paired with a new partner. Asynchrony in moulting, and consequently in courtship, generally ensures that successful parents of one season do not again mate with each other in the following season.

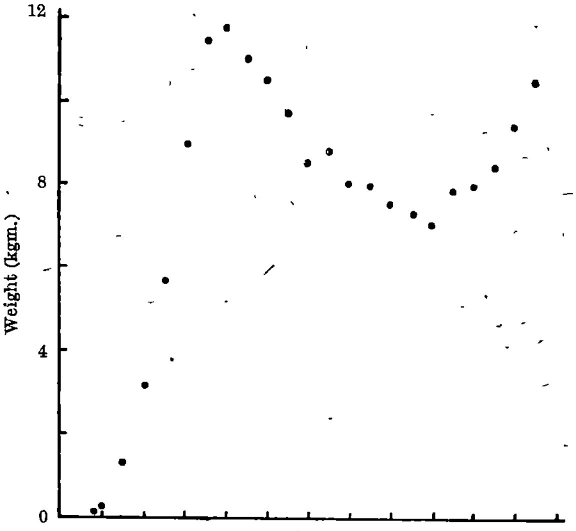

Fig. 3. Bi-monthly weights of a chick from hatching to onset of moult

The problem of fitting a long breeding cycle into a year divided by marked seasonal changes is faced by all large birds of high southern latitudes. The royal albatross (*Diomedea epomophera*)[5,6], possibly also the wandering albatross (*D. exulans*), takes a full year to complete its cycle and breeds only in alternate years. Emperor penguins breed annually but are unique in laying their eggs immediately before mid-winter; the chicks lose their down precociously and are ready for the sea when the fast ice breaks in January and February[7]. The period in which their eggs may be laid is apparently restricted to about a month in all three species. King penguins, which can lay during November–February with every chance of rearing their young successfully, achieve a compromise in being able to raise two chicks in three years. Early breeders of one season, particularly those efficient parents which dispose of their chicks rapidly in spring, may become the successful late breeders of the second season. In the third season they fail to breed, but start again as early breeders at the beginning of the fourth.

Several lines of evidence suggest that king penguins are once again increasing in South Georgia, and are re-colonizing other breeding areas from which they were exterminated during the nineteenth century. These investigations were made on behalf of the Falkland Islands Government, and a full account will be published later in the series of Falkland Islands Dependencies Scientific Reports.

NIKOLA TESLA (1856–1943)

By E. J. HOLMGREN
Canadian Armament Research and Development Establishment, Valcartier, P.Q.

TO-DAY, with scientific research conducted by teams rather than individual workers, the lone research worker who in flashes of genius ventured into the uncharted regions of science belongs to the past. One of the most remarkable, if not the most audacious, of these men was Nikola Tesla, many of whose ideas are now commonplace.

Tesla was born a century ago at Smitjan, Lika, in Yugoslavia. He received his earlier education there, at the neighbouring town of Gospic and at Karlovac in Croatia, and it is said of him that even at this time he displayed unusual abilities in mathematics and science. In 1875 he entered the Polytechnic at Graz, graduating in 1878 and proceeding to the University of Prague for graduate work, which he completed a year later.

At this time Tesla's attention was attracted by the invention of the telephone by Bell a few years earlier, and hearing of an exchange being built at Budapest, he proceeded to that city, and when the exchange was completed he was placed in charge of it and had soon patented a telephone repeater for use there. From Budapest, Tesla went to Paris and thence he emigrated to the United States—a step that was to lead to his greatest single achievement. For a time he worked with Thomas A. Edison in the latter's New York laboratory, designing electric machinery; but as Edison favoured direct current for all electrical applications and Tesla favoured his new theory of alternating current, the differences created forced Tesla to leave and proceed to Pittsburgh, where he received an offer from George Westinghouse, who as a rival of Edison was interested in the possibility of alternating current.

It was here that Tesla's theory of alternating current became reality. The principle of alternating current had been known for some time, but the problems of vibration and stalling of motors had baffled all. Tesla neatly solved the problem by replacing the single circuit hitherto used by several circuits carrying the same frequency but out of step with each other; in this way smooth running was achieved as in a multi-cylinder engine. With improvements in the motor came the development of the alternating current generator and transformers.

Legal troubles over patents in this field forced Tesla to leave Pittsburgh and return to New York, where he opened a private laboratory in which he carried out research in a variety of aspects of electrical fields, including generation of high-frequency currents, transmission of energy over single wires without return, methods of conversion, oscillatory charges and mechanical vibration. He described an electronic valve, but there the matter rested; it remained for Fleming and others to bring this to fruition. At one time he publicly demonstrated the control of a ship by wireless, and visualized (more prophetically than he may have then realized) future wars being fought by robots; although he saw his ideas as a benefit to mankind rather than for its destruction. At one stage he conducted a series of experiments in Colorado to prove the Earth a conductor, and about 1901 opened a laboratory on Long Island, where he conducted experiments into such phenomena as high-frequency oscillations and radio waves and discovered what are now regarded as the fundamental laws of broadcasting, although he did not actively enter the field. The Long Island laboratory, however, closed in 1916 because of financial troubles.

The only field outside electrical research in which Tesla actively engaged was in his development of a steam turbine; but as the ideas of Curtis, de Laval and Parsons were by now firmly established, his idea never progressed beyond the prototype stage. However, like Parsons, Tesla visualized the gas turbine.

Tesla's final years were largely given up to theoretical research, much of which was never committed to paper. Financial difficulties forced him into retirement, and there can be little doubt that many secrets went with him to his grave when he died in New York, early in 1943.

In retrospect, Tesla presents an enigmatic figure, who made a sudden appearance on the scientific scene with one outstanding contribution to electrical engineering and then to put forth many ideas which seemed to lead nowhere. Undoubtedly his greatest contribution was his development of alternating current, with all its ramifications, as witnessed by the pioneer station at Niagara Falls in 1896 (although he played no part in it), and above all the availability of electricity generated economically. It was a crowning achievement in the astonishing development of electric power from its discovery by Faraday. But it is, after all, in his research in the realms of high-frequency current that his contribution remains baffling, for while he made what were later regarded as fundamental discoveries, he seldom brought any of them to reality and in some cases published nothing on them. The failure to do this can possibly be attributed to the non-existence of the research laboratory as we know it, and to the fact that the then infant electrical industry preferred to consolidate its gains in the light of tried ideas rather than embark on anything new. Then the sensational discoveries of Röntgen and of the Curies may have turned attention away from Tesla and his work. Finally, Tesla's habit of almost always working alone may have had not a little influence on his work going unnoticed, for he was no teacher and so never was attached to a university, where he would have gathered around him a circle of brilliant young men who could have carried on his ideas and brought many of them to fruition.

International acclaim came to Tesla, particularly as a result of his work on alternating current, and he was invited to address learned societies both in the United States and Europe, among these being the Institution of Electrical Engineers in 1892. In 1893 he received the Elliott G. Cresson Gold Medal of the Franklin Institute for original work presented before the Institute.

Although he left many of his ideas unpublished, Tesla was a prolific writer and a holder of many patents. Two of his books on high-frequency currents and on his other researches reveal his stature as a scientist, for here he describes complex phenomena that have only recently become to be understood. But if Tesla aspired higher than his era was prepared to accept, it must be stated that he aspired in the finest sense, for as he said in London at the Institution of Electrical Engineers in 1892, his aim was "to advance ideas which I am hopeful will serve as starting points for new departures". In this he was successful.

Nikola Tesla may be likened to an explorer who reaches the summit of an unconquered peak and then waits for a support party to consolidate his newly found gains. That done, he proceeds to survey the unmapped untrodden territory beyond and to report on it; but those who follow must often spend much time wandering, often aimlessly, in these realms ere they rediscover their secrets, often without recognition of the first discoverer. Perhaps these are the misfortunes of the idealist; yet the apparent idealist is he who often points the way for others, and therein is the secret of the noble aspirations and greatness of Tesla.

GENERALIZATIONS ON THE APICAL MERISTEM

By Prof. C. W. WARDLAW

Department of Cryptogamic Botany, University of Manchester

ALTHOUGH the vegetative shoot apical meristems of vascular plants show very evident differences in histological organization, they all give rise to a vascularized leafy axis. That such apices have some organogenic property in common thus presents itself as an inescapable fact[1]. There is therefore a need for concepts that will have a general application to apices, irrespective of their histological patterns.

During recent years a group of French botanists, under the leadership of Plantefol[2] and Buvat[3,4], have been active in histological investigations of vegetative (and floral) meristems of vascular plants, this work having been stimulated by a new theory of phyllotaxis by Plantefol. Among their main conclusions, the following are of special interest: (1) Leaf primordia originate in a superficial ring of actively meristematic tissue, described as the *anneau initial* (initial or initiating ring), which is situated around the base of the inert, or relatively inert, distal apical zone. This *meristematic ring* is regarded as a self-perpetuating embryonic tissue. It is held to be the true vegetative meristem, which would, therefore, be sub-terminal and lateral, and not distal as has so long been thought. The most distal zone of the apex is thus considered to be unimportant in histogenesis and to have no effective part in organogenesis during the vegetative phase. (2) The inception of leaf primordia in the meristematic ring is part of the theory of phyllotaxis proposed by Plantefol[2]. This states that the phyllotaxis of most plants can be referred to a small number of foliar helices. At the extremity of each of these, in the meristematic ring, there is a generative centre which gives rise to all the leaf primordia on that helix. The activities of the several generative centres are harmonized by an organizer which is present in the apex. A generative centre is held to be a physiological, rather than a recognizable, morphological unit. While some investigators[5,6] claim that the theory has been verified by experimental treatments of the apex, others[7-9] have expressed or implied disagreement with it.

In a contemporary monograph from the French school, Camefort[10] has taken up my point about the need for general concepts relating to the shoot apex[1], and has suggested that a meristematic ring (*anneau initial*) may perhaps be present in the apices of all vascular plants. He has, moreover, suggested that, within this concept, it may be possible to interpret the structural differences in the apices of Spermatophyta. He points out that the difference in activity between the allegedly inert apical zone and the meristematic ring may vary according to the species. Where this difference is profound, as in some gymnosperms, for example, in *Picea*, the distal region tends to be homogeneous and a tunica is absent; where it is less pronounced, as in the angiosperms, a tunica is present. In his view, the absence or presence of a tunica is thus associated with a more or less pronounced difference in activity between the apical region and the meristematic ring. Where the summit of the apex is histologically heterogeneous, as in *Taxus*, *Ginkgo*, and *Cedrus*, the superficial cells are cytologically less inert than the underlying 'central' cells. The histological patterns in such apices could be regarded as being intermediate in character between angiosperms (with a tunica), and those gymnosperms which have a homogeneous distal region. In all this diversity of apical construction, says Camefort, the presence of a meristematic ring is the permanent, fundamental fact: the homogeneous meristem, the heterogeneous meristem and the stratified meristem are indicative of successively smaller differences respectively between the activity of the meristematic ring and the apical zone.

Camefort has undoubtedly put forward an interesting generalization which deserves to be more fully investigated. In 1953, I[11] had already indicated that, in attempting to understand the characteristic histological organization of any apex, the size and metabolic properties of the embryonic cells, and the distribution of growth in the apex as a whole, must be considered. Also, although the French workers have stressed the activity of the meristematic ring and its importance as the site of leaf inception, this idea is not in itself new. Already, in 1936, Schoute[12] had advanced the idea that the apex consists of several physiological zones, or levels, which in my[13] terminology and conception would include, in basipetal sequence: (1) the most distal region, which, in ferns, would include the apical-cell group; (2) the sub-distal region in which the patternized distribution of metabolites associated with the inception of growth-centres takes place; (3) the organogenic region in which the formation of primordia from the growth-centres can be observed; (4) the sub-apical region in which conspicuous enlargement takes place; (5) the region of maturation. The meristematic ring of the French school would comprise regions (2) and (3). The inertness attributed to the most distal region is, it need scarcely be said, a very controversial matter and has already been the subject of criticism[14–16].

The morphological phenomenon of greatest generality is that the shoot apices of almost all vascular plants give rise to regularly spaced leaf primordia. This, of course, has long been recognized. The observation, however, acquires a new importance if it is restated with reference to the antecedent and underlying physiological processes, namely, that in the peripheral tissue of the sub-distal region of all apices, in which the embryonic cells are seemingly homogeneous, a patternized distribution of metabolites apparently takes place. This results in the accumulation, concentration, or formation, in more or less well-defined and characteristically spaced loci—often described as growth-centres—of substances actively involved in growth and cell division. Turing[17] advanced a physicochemical theory to explain how a pattern of metabolites might be brought about in an embryonic tissue in which the substances were initially more or less homogeneously distributed, and I[13,18,19] have suggested how this, or some similar physicochemical theory, might apply to very diverse organogenic and histogenic developments in plants. Turing, moreover, postulated that quite differently constituted reaction systems may nevertheless give rise to closely comparable morphogenetic patterns. If this concept can be shown to be valid, it will evidently go a long way towards explaining the many parallelisms of development (or homologies of organization) to be observed in plants. In particular, it will have an important application to the general phenomenon of apical activity now under consideration. The growth-centres, however we may explain their origin, usually grow out as localized mounds on the surface of the apex and develop as dorsiventral leaf primordia. It is a very remarkable fact, and again one of very wide generality, that, in microphyllous and megaphyllous species alike, the primordium at its inception is multicellular and comprises both surface and sub-surface cells. Even the very small, non-vascularized, scale-like microphylls of *Psilotum* are covered by this general statement. In the angiosperms also, the different organs of the flower all have their inception in similar multicellular growth centres.

It is relevant to inquire to what extent the generalization that all shoot apices have the inherent property of giving rise to foliar primordia is borne out by the fossil evidence. Here we come upon a very remarkable state of affairs, remarkable not because the evidence has been neglected by botanists, but rather because concentration on, and perhaps over-emphasis of, the inferences that can be drawn from it from one point of view, seem to have obscured other not less valid inferences. Thus, the ancient Psilophytales, in particular such organisms as the leafless species of *Rhynia*, have been accepted by many botanists both as affording an evident basis for the phylogenetic treatment of the vascular plants, and as providing essential evidence relating to the evolution of the leafy shoot. The discovery of Palæozoic plants, with a bifurcating, leafless and rootless axis, such as *Rhynia*, has enabled morphologists to envisage a 'prototype' or 'archetype' from which the more advanced classes of vascular plants, all characterized by leafy shoots, might have originated. But, on the evidence, *entirely leafless* vascular plants, whether on the 'evolutionary upgrade', or as the result of 'reduction' from some leaf-bearing ancestor, appear to be very rare. The only completely leafless vascular plants known to us belong to the Psilophytales, for example, species of *Rhynia*, *Horneophyton*, *Zosterophyllum*, etc. Other species considered to be of this affinity, however, had an axis covered with evident microphylls, for example, *Asteroxylon mackiei* and others had small scale-like lateral organs. The very ancient fossil, *Baragwanathia longifolia*, of Silurian age, had an axis with abundant microphylls. Many vascular plants, contemporary with the Psilophytales, but belonging to other classes, are known, and these all had leaves. It is therefore an open question whether the entirely leafless genera of Psilophytales were not exceptional in their organization, rather than archetypic of all other classes of vascular plants as has so often been assumed or implied. Indeed, the possibility that they may have been reduced forms in relation to special environmental conditions cannot be excluded[20,21]. The existence of other classes of vascular plants of at least the same antiquity as the Psilophytales, all characterized by foliar development, widens the scope of the generalization under consideration. Lastly, without entering into details, it may also be noted that in the gametophytes of mosses, and in some of the larger brown algae, organized apical meristems are present which give rise to regularly spaced lateral organs.

As we have seen, the importance attributed to the meristematic ring in organogenesis derives from

Plantefol's phyllotaxis theory of multiple helices. According to the theory, each leaf-generating centre moves acropetally (by some mechanism not explicitly specified) along a helical path in the apex. Its actual location is in the meristematic ring where, from time to time during the growth of the apex, it gives rise to leaf primordia[22]. The majority of dicotyledons are considered to have two foliar helices, these having their beginning at the inception of the two cotyledons; and if there are three cotyledons, then there are three helix-generating centres. As an apex enlarges during the ontogenetic development, the number of helices may increase, this being attributed by the French workers either to the formation of two centres from an orginal centre or to the intercalation of a new centre between two existing ones.

Thus, as I understand the theory, in order to account for *the inception of the several helices*, it is necessary to assume that a pattern of growth-centres can originate spontaneously in the apex, beginning with that of the embryo. As I have attempted to show, and have indeed emphasized, this property, or functional activity, of apices is a phenomenon of the widest generality in plants. It is particularly evident in the embryos of species of *Pinus*, for example, *P. ponderosa*, where, in direct relation to the size of the apical meristem, 6–16 evenly spaced cotyledon primordia originate simultaneously in a ring around the meristem, there being no pre-existing lateral organs to exercise regulative effects of any kind. Again, in Rubiaceae such as *Galium aparine*, and in species of *Equisetum*, etc., the ontogenetic development is characterized by an increase in the number of foliar members at successively higher nodes. These and many other instances afford evidence that characteristically spaced growth-centres are determined by factors inherent in the apex, this, in my view, being one of the basic and essential features of the organogenic development of the leafy shoot. Where leaf primordia are already present, the morphogenetic situation in the apex is much more complex. Observation and experiment indicate that the positions of growth-centres (and of the primordia to which they give rise) are affected by the young primordia which surround the apical meristem, a new primordium typically originating above and between two adjacent primordia[23]. It is also relevant to note that primordia always originate in the apical meristem at some characteristic distance below the extreme tip (or centre). This distance varies with changes in the size of the apex during the ontogenetic development, and it can be modified in characteristic ways by various experimental treatments. The overall organization of the apex, and the integrated physiological activities of its component regions, must, therefore, also be given due consideration in the analysis of organogenesis and phyllotaxis.

It will be noted that while ideas relating to growth-centres, or to the helix-leaf-generating centres of the French school, may be stated in different terms according to the individual investigator's approach, there appears to be a considerable measure of agreement on several points, notably, that growth-centres have a real existence as loci of special physiological activity, that they are formed at some characteristic distance below the tip of the meristem, and that they are characteristically spaced around the apex. In my view, however, a growth-centre is a discrete physiological unit occupying a particular position in the meristem, so that there are as many growth-centres as there are leaves, whereas in Plantefol's theory, each leaf-generating centre retains its pristine physiological properties and moves acropetally around the apex, giving rise at intervals to leaf primordia. The latter collectively constitute a foliar helix.

Snow[7,8,24] has shown that the theory of multiple helices is open to criticism on several grounds. We may also note that Plantefol's theory brings its own difficulties when he attempts to explain floral ontogenesis[25]; for whereas the sepals are regarded by him as foliar members arising on the vegetative helices, the petals, which in many flowers also have the form and structure of leaves, are considered not to be homologous with leaves but organs *sui generis*. Camefort[10] has not attempted to answer Snow's criticisms, and, indeed, states (p. 102) that the only causal theory of phyllotaxis that attributes a direct role to the vegetative apex in the positioning of leaves is that of Plantefol. In this, he appears to overlook the results of experimental investigations in which the self-determining nature of the apex in organogenesis has been demonstrated and duly emphasized[26–28], as well as views based on Turing's theory[13,17–19].

When considered in terms of the underlying physiological mechanism, the theory of multiple helices raises new problems of great complexity. This, of course, is not in itself an argument against the theory, and, indeed, we may recognize that the investigation of apical organization and organogenesis not only bristles with difficulties, but also that these may well increase rather than decrease with new accessions of knowledge. As I have indicated above, the postulated acropetally moving leaf-generating centres of the French school must have their beginning in a pattern of growth-centres. If, therefore, the concepts (*a*) of the inception of discrete growth-centres in the sub-distal region, as determined by genetical and other factors and relationships, (*b*) of the regulative effects of existing primordia on new ones, and (*c*) of the functioning of the shoot apex as a regulated and integrated whole, are taken together, the theory of phyllotaxis advanced by Plantefol appears to be unnecessary, while the new facts ascertained by the French workers can be assimilated to other views on apical growth and organization.

TECHNOLOGY OF ANCIENT GLASS AND METAL

THE general theme chosen by Section H (Anthropology and Archæology) of the British Association for the Sheffield meeting was entitled "Technology of Ancient Glass and Metal".

Dr. D. B. Harden, in discussing "Ancient Glass Furnaces", complained that the archæological evidence is very poor. Sir Flinders Petrie recorded an Egyptian furnace dated to 1350 B.C., and in general the Near East seems likely to produce valuable material, as it has done in the past. But, in north-west Europe, there is scarcely any evidence earlier than A.D. 1000, and most of the data refer to much later periods. This situation is in strange contrast to the many pottery-making sites of various periods which are known. Our knowledge of ancient glass-making still depends too much on documentary sources such as Theophilus and Agricola. The discovery of a Late Saxon glass-working site at Glastonbury Abbey in Somerset last year is therefore important. Mr. Ralegh Radford has to date found remains of two furnaces there, as well as fragments of furnace pots with glass adhering and evidence of glass-blowing. The furnaces appear to have been built on a mortar floor laid in a pit, and against the clay sides of the pit. The upper parts were probably domed over with clay stiffened by re-used Roman tiles, and buttressed with stones. It seems that heat was supplied by external fires piled over the roof. The smaller of the two furnaces was possibly for annealing, and the larger for the pots.

Prof. W. E. S. Turner, in reviewing our knowledge of "Raw Materials and Composition of Ancient Glasses"[1], directed attention to the constancy of recipes with regard to the main constituents: sand (or crushed silica rock) and ash (or glassmaker's salts). By 1700 B.C., the time of the earliest known reference, glassmaking was well established in Babylon: four different glazes are described, containing saltpetre, lime, copper, lead and, as the main constituent in each instance, a glass of which no details are given. Although lead occurs in this recipe, fewer than 10 per cent of 500 glasses analysed, ranging from 1500 B.C. to A.D. 1700, contained more than 0·5 per cent of lead oxide. The great majority were of the alkali – lime – magnesia – alumina – silica type. Lime, again, appears in the Babylonian text but the quantities (from 5 to 12 per cent) found by analysis in ancient glasses are far greater than any prescribed. In general, the composition of the glasses is very complex; ten to twelve constituents were found in many of the earliest specimens.

Alkali is first noted on Assyrian tablets of the seventh century A.D., as ash from the plant *Salicornia*. Soda could have been obtained from the natron lakes of Egypt or, with potash, by burning plants or trees. Coastal or desert plants give more (reactive) soda than potash, inland plants more potash, and all types also have lime and magnesia in their ash, in some cases (for example, beechwood) more of these than of the alkalis. Until the Middle Ages, glass always contained much more soda than potash.

Lime would enter glass also with the sand, where it can be present as shell detritus in amounts larger than 10 per cent. Similarly, magnesia and alumina would be transferred in quantity, and the lowest iron oxide content of eight samples of sand from possible glassmaking sites was found to be 0·15 per cent.

Lead glasses were mainly opaque and coloured. Large quantities of barium have been found in Chinese beads of about 200 B.C. but in no other case. Black glasses coloured with iron oxide are known from the second century B.C., and manganese is common even in early specimens, sometimes exceeding 5 per cent. The earliest coloured glasses are blue; usually copper, but sometimes cobalt, is found to be the cause, throughout the whole period. Cuprous oxide (up to 12 per cent) is present in the sealing-wax red glasses. Antimony occurs occasionally but arsenic scarcely ever, and then only in traces.

"The Analysis of Ancient Glasses" was considered by Mr. E. M. Jope who, like Prof. Turner, stressed the difficulties involved in, and yet the necessity of, carrying out complete chemical analyses. Even then the results give no indication of the intentions of the ancient glassmakers, although we can judge their powers of selecting raw materials and their knowledge of colouring agents. In order to appraise their skill we must, furthermore, know the workability of their material. The development of quantitative spectrometry in this connexion would greatly benefit research despite the limitations of the method.

For example, copper is easily incorporated into soda glass, the cupric ion giving a green or blue colour according to the value of the soda/silica ratio. On the other hand, cuprous oxide presents considerable difficulties: if about 10 per cent is present in glass frit it can give either the desired red, opaque enamel or glass, or a colourless or faintly green glass, according as the temperature is kept below, or allowed to rise above, about 1,030° C. The presence of lead in such red glasses, as early as the second millenium B.C. in Egypt, suggests that its fluxing value was already appreciated at that time.

Similarly lime, alumina and magnesia affect the properties in various ways. The composition is thus a precise index of the problems of the ancient glass-worker, and the manner of their solution, in making some of the remarkable pieces which have survived. The greatest achievement was clearly to bring high enough temperatures to bear precisely where required, and to carry out a complex operation rapidly in the short time available. The excellence of some ancient techniques can be fully realized, however, only when one tries to copy them using the primitive means then available.

Mr. Jope briefly discussed the analytical values required and the methods which were suitable and available. It is important to know the refractive index and the softening and hardening range. The study of residual strains with the polariscope is profitable in the case of complicated work such as applied decoration. Newer techniques seem promising, especially when automatic and comparatively rapid or extremely sensitive, but the X-ray fluorescence method, for example, is not applicable to the study of sodium and potassium content for which flame photometry remains most useful.

These methods were also listed as aids in "A Technological Research Programme on Ancient

Glass" by Mr. Ray W. Smith, whose paper was read by Dr. Harden. Other techniques briefly described included X-ray diffraction and neutron activation, with examples of their successful application to problems of decay and composition. Microscopic examination will elucidate stains and imperfections, and manufacturing techniques in general. The study of bubble patterns will be an important factor. Although quantitative chemical analysis remains the most reliable method, spectroscopy has become an invaluable aid. X-rays appear to darken glasses, giving a smoky or even markedly purple tinge, but this is temporary and moderate heat removes it quickly.

Mr. Smith's programme suggests the collaboration of properly equipped laboratories all over the world, with the aid of adequate subsidies, on a long-term project for clarifying the composition and properties of ancient glass. After a preliminary phase when methods are critically examined, a selection of the most useful techniques is to be generally accepted so that results can be compared. The first phase of the work will determine the general nature of a number of specimens from well-known areas and periods. This will establish about a hundred normal, 'standardized' groups classified according to age and location. The second phase is to study raw materials, particularly major constituents and such of the minor elements as appear to be distinctive.

The third phase will collect deviations from the norm and examine special aspects. The whole project is designed to produce a set of criteria for dating glass on technological grounds.

In the course of the discussion, Dr. E. T. Hall said that the Research Laboratory for Archæology, at Oxford, is prepared to consider constructive proposals about analysis of glasses. In each case there will have to be a definite research problem, and a scheme of work together with full discussion is required.

Prof. W. G. Fearnsides began the session on ancient metal with a paper on the "Distribution of Metalliferous Ores" in the British Isles. At the start of the Bronze Age the dense vegetation cover made mineral discovery difficult except on steep slopes, cliffs and beaches. The distribution of finds shows an obvious preference for chalk hills, limestone plateaux and gravel terraces, and bears little relation to the pattern of metal-bearing areas.

The Trias sandstones of Alderley Edge are the youngest deposits to have been exploited for copper. In the Carboniferous Limestone cliffs and caves along the Derwent valley, the North Wales coast and inland to Oswestry, numerous lead veins are accessible, in some places also copper and zinc; and very early lead workings are known in the limestone dales of West Yorkshire, in high Teesdale, and in tributary valleys of the Tyne. Lead is similarly present in limestone around the South Wales coalfields and the Forest of Dean (with iron), and in the Mendips (with zinc and silver).

By far the richest area lies in a ten-mile wide belt stretching from west of Penzance to east of Tavistock; here veins from Cornish and Dartmoor Carboniferous granites cut across Devonian sediments. Having escaped glaciation, this area presented to early man a typical weathered surface rich in coloured and easily accessible deposits, similar to conditions in Spain and the Middle East, and quite different from Wales and most of Ireland. Also, a large quantity of heavy minerals including tin had been washed into river valleys by Tertiary weathering.

There has always been much more copper than tin in this area. The enrichment zones could have produced all the copper and alloying metals found in British early bronzes. But Prof. Fearnsides' practical experience has convinced him that it would be impossible here to hand-pick even a hundredweight of ore which would smelt to a Bronze Age alloy of the proper proportions. He feels sure that for centuries before any tin bronze was made in Cornwall, there was export of Cornish alluvial cassiterite to metallurgically more advanced centres in the Mediterranean area and Middle East. No tin occurs in Wales, the Lake District or Scotland, and very little in Ireland where, however, some bright weathered copper deposits could have been seen and got without much digging.

The iron ores first used were evidently clay ironstones from the Lower Cretaceous Wealden forest area in Kent and Sussex, some of the Jurassic weathered oolites (that is, limonites) outcropping under Oolitic Limestone between Oxfordshire and Lincoln, Lower Lias south of the Humber, and Middle Lias of the Cleveland Hills—all low-grade deposits but more manageable than better ores. There is evidence of working, in all the cases mentioned, by Roman times, when also hæmatite in the Carboniferous Limestone of the Forest of Dean and the Vale of Glamorgan, near Barrow-in-Furness and in Cumberland was used on a large scale.

Prof. F. C. Thompson next dealt with "Mining, Extraction, Refining and Casting", mainly of copper, and the production of alloys. Antler picks and wooden shovels would be sufficient for mining soft, weathered deposits; in other cases, fire-setting (alternate heating and water-quenching of an ore face) is known to have been used in 2000 B.C. The advantages of concentration by hand-picking, crushing and washing would have been seen quite early.

Simple carbonate ores are directly reducible by heating with charcoal at a dull red heat; lead, also, is easily obtained in this way whereas iron and tin are more difficult; this explains why copper was the first metal obtained by smelting. Copper approaching native metal in purity can be obtained from carbonates, but the spongy mass produced is not easy to deal with until melting is achieved; this requires some form of blast.

Sulphide ores are first roasted in air; although this may be done on a simple platform of fuel and, once started, is self-continuing, success requires skilful and constant control. Simple sulphide ores are thereby converted to the oxide which, like the carbonate but *not* the sulphide, is reducible with charcoal. Complex sulphide ores usually contain much iron, which must be removed completely, as well as arsenic, antimony, zinc, nickel, etc., which will enter the copper metal in proportions depending on conditions. Arsenic and antimony, for example, are partly volatilized on roasting, but their higher, more stable oxides will also be formed, and will afterwards be reduced with the metallic oxides. There is thus no direct correlation, for such impurities, between the contents in an ore and in the metal obtained from it. Far too much importance has been attached by archæologists to variations in composition which are often only to be expected from normal practice in early times.

Roasting replaces sulphur by oxygen, which on smelting preferentially attaches itself to the iron, and

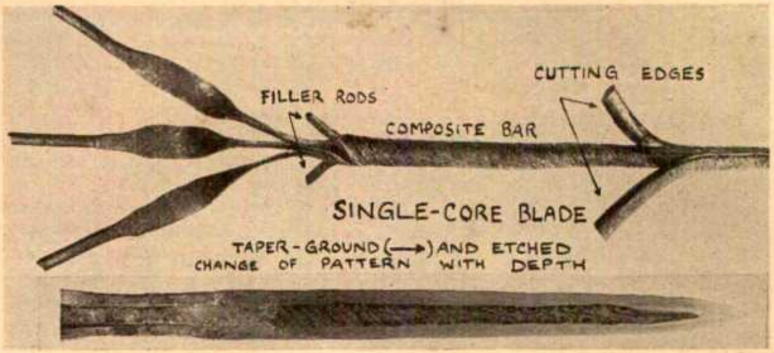

Fig. 1. Modern pattern-welded sword: experiment No. 7. (See "Technology of Ancient Glass and Metal": contribution by J. W. Anstee)

the resulting iron oxide can be slagged off by adding sand to the molten mass. If much iron is present, the roasting and smelting may have to be repeated several times before the final product is free enough from iron, can be dead-roasted to copper oxide, and finally reduced with charcoal to the metal. But all the operations are well within the means of primitive man, and it is obvious that sulphide ores were smelted successfully before 2000 B.C.

As the quality of ores deteriorated, impurities in the metal increased, but sometimes also gave a product that was harder and easier to cast. This gradually led to deliberate alloying attempts, as for example in an object with about 7 per cent of arsenic and all other impurities less than 0·05 per cent, and ultimately in the true tin bronzes.

At a certain stage there is a change that suggests the use of fire-refining which, with poleing, could make copper from impure ores as pure as that won from hand-picked malachite. The pure tin bronzes of this and later periods could have been made only by smelting tin ore with such refined copper and not, like earlier bronzes, from mixed ores.

Mr. H. Maryon followed with an account of the development in the "Fashioning of Metal Artefacts"[2]. Observation of the earlier mobility of some (that is, the more impure) metals during a melting run may have suggested the process of soldering. Hard soldering (above 550°) dates back to 3400 B.C. and was common practice in Ur; soft soldering was known before 2500 B.C. Extremely fine granulation work was produced by the Greeks and Etruscans in the sixth century B.C. Often wrongly described as 'welded', non-ferrous metal joints were invariably soldered, with the exception of a set of small gold boxes (Early Iron Age) showing cold lap welds. Repairs were often made by 'burning (or running) together': the fracture was, in effect, enveloped in a clay mould and fresh metal was cast on.

The oldest metal statues were made of copper sheets either riveted or nailed to wooden cores, and riveting was also common in domestic ware and for decoration. Bowls were made from early times by sinking (hammering on the inside) or raising (from thin sheet by hammering on the outside), and there are thousands of early examples of repoussé, chasing and engraving, as well as of work done with tracer or punch, or in high relief. All these processes require much annealing and the products show that this was well understood. Other methods of decoration were 'inlay', that is, the tracing of a recess into which a piece of another metal was inserted and fixed, and 'overlay', which involves attachment by cold flow to a surface that is merely roughened and not recessed.

Ferrous (true) welding is in evidence from the beginning, as in a tiny model head-rest of Tutankhamen (1360 B.C.). Warriors of Asshur-nazir-pal had iron swords (ninth century B.C.), and the Luristan finds (1200–900 B.C.) show some steel containing 0·5 per cent of carbon, demonstrating that forging and carburization developed quickly. Ultimately welding also came to be used successfully in massive structures such as the Colossus of Rhodes (280 B.C.; 7½ tons of iron frame) and the Delhi pillar (A.D. 310; 6 tons), as well as in delicate work, involving the 'piling' of many sheets into a composite laminate, and developing into pattern-welding.

Mr. H. W. M. Hodges, in his "Studies of Ancient Metal-working Techniques", put forward evidence suggesting the influence of other technologies in the Bronze Age, with examples from Northern Ireland. The finishing of sandstone or steatite moulds harked back to Neolithic stone working, and the form of cast implements was dictated by the limitations of carving in stone. Clay moulds usually consist of an inner (fine) and outer (coarse) sheath. Particle size and mineral analysis of moulds (for swords) found in Lough Eskragh has shown that the clay in both sheaths came from the same deposit, but that the inner sheath had been made of levigated material, as used in making slips and thus showing the potter's hand. The patterns for such moulds were often made of wood (as found at Tobermore, Co. Derry). Wood grain is evident in some bronze implements, and casting is here dependent on wood-carving technique. Casting in two-piece moulds made of bronze, and running-on, appear to owe nothing to other technologies, although bronze shields and early cauldrons, for which there are no bronze prototypes on the Continent, may be copies of leatherwork.

Mr. J. W. Anstee described a series of nine experiments to determine the essential features of a method of making "Pattern-welded Iron Swords". All the work was carried out single-handed under primitive conditions, using a small forge with Chinese-type box bellows, hammer, tongs, vice and a crude anvil. Supplies of home-made charcoal were insufficient (about two hundredweight would be required for one sword) and coke was used in all cases except three.

The first six experiments served to eliminate various points of technique as being impossible or unnecessary. No. 7 produced a specimen sword in which the various stages were left unfinished to show the details of the method (Fig. 1). No. 9, a similar but fully finished sword, was produced as follows. Three rods of good, Victorian wrought iron, each 0·22 in. in diameter, were forged out into strips in which the ratio of width to thickness was 9 : 1. The strips were laid flat one on the other and forge-twisted into a two-start screw, two 'filler rods' of square section being at the same time incorporated into the valleys. The resulting composite bar was flanked on either side by a straight packing rod, and by another composite bar of opposite twist the units of which had undergone a home-made case-hardening treatment. This assembly was forge-welded together, using a sliding wire-clip and proceeding in inch-heats, to give a triple band of characteristic herring-bone pattern, tapering to a point at one end where it had been gripped by the tongs.

Cutting edges were welded on to this core by doubling a forged half-inch rod around the point. Fullering, final forging, and grinding completed the sword blade for which a hilt, scabbard and belt fittings were also made. The total working time was seventy-five hours, of which forty-three had been spent on the blade, involving 128 separate forging and welding heats. The finished blade weighed 1 lb. 10 oz.; 1 lb. 3 oz. had been removed from the rough forging by grinding, and the total cross-sectional area of the original core-assembly had been reduced by 70 per cent. The work showed that any of the patterns observed on ancient swords could be produced in this manner by twist-welding and grinding.

Two speakers dealt with "Scientific Evidence about Metalworking Techniques". Mr. L. Biek showed how Mr. Anstee's research had been suggested by observations made while cleaning the Westminster Sword (ninth century) on the change of pattern with distance from the surface (Fig. 1), and how (*a*) radiographic examination, and (*b*) metallographic study (at the National Physical Laboratory), had helped at various stages. Most pattern-welded swords are so corroded that (*b*) is not possible; on the other hand, a sound sword does not lend itself to (*a*). It is thus difficult to obtain a good correlation, especially as the methods are most useful at different magnifications.

The Westminster Sword has, however, been examined in both ways, and a direct metallographic comparison with Mr. Anstee's No. 7 has been made. The older specimen is homogeneous and contains about 0·2 per cent of carbon, while the other is virtually free from carbon but carries slag inclusions which are responsible for the pattern seen on the polished and etched surface. Pattern can thus be produced even when there is no alternate layering of wrought iron and steel.

Dr. E. Voce demonstrated the value of interpreting the metallographic record[3], left on copper and bronze objects, of the manner in which they had been produced. In some cases, particular combinations of structural features allow one to give detailed descriptions of certain points in an object's history that cannot be determined on any other basis. Thus a Scottish celt which has clearly been cast shows an annealed structure but no evidence of any working. It appears therefore to have been heated, after manufacture and for no metallurgical reason, possibly in a ritual fire. Again, cuprous oxide inclusions in the wrought and annealed structure of a ring from Azarbaijan prove that it could not have been made from unmelted native copper.

Mr. H. H. Coghlan described the results of recent spectrographic and chemical analyses of artefacts and ores[4], made in an attempt to provide "Scientific Evidence about Provenance of Early Implements". The analysis of more than a hundred British artefacts has shown, as previous workers had found elsewhere, that the results fall into groups which are sufficiently well defined to justify the work within the chosen limits. Although, as Prof. Thompson said, the figures must not be taken too literally, whole series of analyses show better agreement than is required by many modern specifications. This is an inescapable fact which suggests that the control of operations may have been better than we imagine.

Broadly speaking, in the large majority of implements, arsenic, antimony and silver are significant impurities, present in uniform quantity and accompanied by certain minor elements which are also fairly constant. Within this group there may be a subdivision into halberds and axes, arsenic and antimony being much lower in the latter while silver remains the same. There are also a small number of artefacts containing more than 99 per cent of copper, evidently not made from native copper but of metal from pure carbonate ore, and some isolated but 'standard' 10 per cent tin bronzes.

A start has been made with likely ore specimens from Ireland and southwest England. The few results so far available suggest that the two areas are distinct in some ways useful for this purpose, while the quantities of arsenic and antimony found in implements are well within the limits of theoretically possible transfer from ore to metal.

Prof. V. Gordon Childe discussed the "Archæological Significance of Metalworking Techniques". The early development of the saw directly affected carpentry, stone-working, architecture and, by making wheels possible, revolutionized transport and thereby other industries. Though wheels and ploughs could have been made with stone tools, neither is known before the beginnings of metalworking. Ashlar masonry was probably impossible without a saw, and seals were normally engraved using metal drills and gravers. Nearly as old is the cauldron, which made possible cooking by suspension.

Later, though still in the Bronze Age, came nails, wire, springs, hinges and adjustable compasses. With the Iron Age came tongs, shears, scythes, horseshoes, tyres and ploughshares. Metal further encouraged the specialization of tools, but the general spread of its influence was limited by cost. Thus flint sickles were usual until the Late Bronze Age and log-cabins do not appear in Europe until after the cheap socketed celt. No intensification of forest clearance is noticed until the Iron Age when, in Norway for example, the first smelting of bog iron ore is followed by a great expansion in this respect. Food production was then also greatly affected by the introduction of iron scythes and other agricultural implements.

Mr. T. W. Farrer concluded with a consideration of "Scientific Evidence from Ancient Artefacts as related to Conditions of Burial". The rate of corrosion of buried metals is dependent on a number of factors which may vary considerably both in space and in time, so that no estimate of age is possible from corrosion products. But as their nature is a reflexion of conditions of burial, it is sometimes possible to tell where a change in these conditions has taken place, from such features as the adhesion of the corrosion products, or the peculiar tuberculation of iron objects associated with fresh-water. Perhaps the greatest single factor is the oxygen concentration, and there is marked difference between the states of preservation of metals according as they are found in well-aerated or waterlogged deposits.

In recent years, corrosion in anaerobic deposits has been closely studied in both archæological and industrial contexts, to great mutual advantage. Thus the protection of buried iron pipes from bacterial attack by the use of tannins, now carried out on an industrial scale, was suggested by well-preserved Saxon ironwork found with leather[5]. Other finds have confirmed industrial research on peaty soils, where similar inhibition appears to be due to the presence of antibiotic substances. On the other hand, this has led to a better understanding of the archæological conditions causing, for example, bright blue patches of vivianite, or particular types of film on metal objects, found in such deposits.

Introducing the general discussion, Mr. L. Biek listed some features common to both technologies: high temperatures, often carefully controlled or applied at selected spots; use of refractories and charcoal; casting, sintering, annealing and soldering, including glass-to-metal joints. Possibly both materials owe their discovery to the same cause—a major fire. The same analytical techniques are used, and variety of approach is needed, including the crucial test of 'doing it yourself'. It is thus most valuable to consider glass and metal together. As a result of the preceding papers and discussion, excavators will know better what to look for, and analysts where methods can best be perfected. They have shown, once again, the great value of such study in revealing not only the astonishing level of some ancient skills, but also points of interest to modern research.

The following emerged from the discussion. Various laboratories analysing early copper implements are in touch with one another, and their results can be compared within the chosen limits of accuracy. Study of isotopic ratios in lead, for example, is not likely to be useful in suggesting provenance as regards the British Isles. Analysis by neutron irradiation is extremely sensitive but not uniformly so. Several speakers stressed the importance of testing archæological hypotheses by scientific analysis and experiment, and the need for provision of more facilities by the larger institutions.

L. BIEK

OBITUARY

Sir Francis Simon, C.B.E., F.R.S.

THE death on October 29 of Sir Francis Simon, barely a month after taking up his new appointment as Dr. Lee's professor of experimental philosophy and head of the Clarendon Laboratory at Oxford, has come as a tragic shock to his very many friends and colleagues.

Simon was born in Berlin in 1893 and studied at the Institut fur Physikalische Chemie there. Later he became professor extraordinary at Berlin and professor and director of the Laboratory of Physical Chemistry at Breslau. When he came to England at the invitation of Lord Cherwell in 1933, he was already known internationally for his work on the physics of low temperatures, and particularly on the heat theorem of Nernst, his former teacher. During the years leading up to the War he then built up a small but powerful school of low-temperature physics at Oxford with the help of his former students, Mendelssohn and Kurti. The accommodation and facilities of the old Clarendon Laboratory being extremely primitive, the activities of this school depended largely on the use of miniature helium liquefiers based on the 'expansion' method which Simon had already developed in Germany. Perhaps the most notable success of the period was his work with Kurti on magnetic cooling, in which the temperature-range below 1° K. was systematically studied.

At the beginning of the War, many foreign-born scientists found themselves left out of the then existing scientific war projects. It is ironic to realize how much the development of nuclear energy owes to this. Simon was one of the chief instigators of the project and, with Peierls, was mainly responsible for the development of the diffusion method of separating the isotope uranium-235, later realized in the enormous diffusion plant at Oak Ridge in the United States. With his wife and two young daughters evacuated to Canada, Simon worked with great energy in the direction of a group at Oxford and on government committees, and made several visits to the United States.

After the War, Simon re-started low-temperature work under the greatly improved conditions of the new Clarendon Laboratory, and quickly built up a school which, by comparison with the pre-war school, can best be described as large and powerful. The range of work of this school in recent years has been outstanding, covering almost every branch of low-temperature physics and linking up with workers in nuclear physics and radio-frequency physics in most fruitful ways. A few years ago their collaboration resulted in the first reported experiments on the orientation of atomic nuclei. Only a few months ago it was reported in *Nature* that Simon, Kurti and their collaborators had achieved a nuclear cooling, reaching temperatures of about twenty millionths of a degree absolute for the first time. This was a project squarely in the low-temperature tradition, and had been close to Simon's heart for more than twenty years since its original proposal by Gorter.

In recent years Simon became a considerable public figure as a vigorous campaigner for the proper development and use of science, which he advocated in books, newspaper articles, on the radio and in public lectures. He was well known on government committees and took a particular interest in fuel policy, about which he campaigned (as it now appears) with some effect. A Fellow of the Royal Society since 1941 and holder of the Rumford Medal, he was made C.B.E. in 1946 and was knighted in 1954. He was honoured by many other scientific societies in Britain and abroad.

Simon's position at Oxford was as reader and later professor of thermodynamics. In his case the title was exactly appropriate. His outlook was essentially thermodynamic and he saw scientific problems simply and as a whole. It is perhaps significant that in his recent Guthrie Lecture to the Physical Society he returned to his first love, the Nernst heat theorem, now elevated to the status of the Third Law of Thermodynamics. A great deal of the work which came from his laboratory was inspired by this Law, and many of our existing ideas about the solid state started as 'anomalies' in the specific heat – temperature curves of Simon and his students. It is interesting to note that although some of the detailed results of his school were later improved upon by workers with more highly developed techniques, his 'hunches' and his interpretations of the results were in almost every case proved correct. His thermodynamic sense extended beyond physics and he would apply the same approach in discussing, say, world fuel or food policy, as to the design of a helium liquefier. He was sometimes old-fashioned in his insistence upon simple methods, and many of his more electronic colleagues have heard him beg, "Can't you do it with d.c. ?". It is perhaps not entirely inappropriate that his last and greatest achievement was an experiment done with direct current.

Simon relied generously on his closest colleagues, many of whom stuck to him for very long periods. It was an exciting experience to take part in a project with him, and the pattern was usually that Simon provided the simple idea and the energy and his collaborators filled in the details. His school expanded so much in recent years that international conferences on low-temperature physics began to take the form of reunions for scores of his former collaborators now working in very many countries, and he fell easily into the role of doyen of low-temperature physics.

Many who did not know Simon assumed that he would be somewhat Teutonic in outlook and expected pedantry and pomp from him. Nothing could be more wrong. His friends and collaborators knew that he was mischievous, mercurial, generous and warm-hearted, always approachable, impossible to offend. Although he still maintained that the English were mad in some respects, particularly in their love of sport and of cold rooms, he identified himself completely with them, and took part with great enthusiasm in college life at Oxford. Generations of research students and hundreds of visiting scientists enjoyed the hospitality which he and Lady Simon offered in their home. He was always delighted when any of his colleagues or his secretaries married each other, as frequently occurred. Whenever he travelled he would send postcards to his colleagues and he kept closely in touch with all who left Oxford, helped them whenever he could do so, and kept each one up to date about what was happening to others. He had many endearing eccentricities, particularly connected with the temperature of his surroundings, and during a long conversation with him a visitor might find that at one time Simon would be wearing cap, muffler and sweater, and that at another time he would have taken them all off and opened the window.

He was a unique figure, and all who knew him are deeply saddened by his death. G. O. Jones

---

NEWS and VIEWS

The Forestry Commission :

Mr. A. H. H. Ross, O.B.E.

Mr. A. H. H. Ross, director of forestry for Scotland since July 1953, is due to retire from the Forestry Commission in March. Mr. Ross obtained a diploma and degree in forestry at Oxford in 1920 and was for some time in the Indian Forest Service. He joined the Forestry Commission early in 1925 as a district officer, serving successively in different areas under the then assistant commissioner for England and Wales. During the War he was engaged on timber supply duties and was with the North German Timber Control. Following his return to the Forestry Commission, Mr. Ross was promoted to conservator of forests for north-west England, with headquarters at Chester, where he remained until his appointment as director of forestry for Scotland. In that office, Mr. Ross has played an important part in the more recent development of forestry in Scotland and is at present in charge of nearly half a million acres of Commission woodlands.

Mr. A. Watt

Mr. A. Watt, who is at present serving as a conservator of forests at the headquarters of the Forestry Commission in London, has been appointed to succeed Mr. Ross. He obtained his degree in forestry at Oxford in 1931. He was appointed a district officer at Aberdeen in 1934 and afterwards served in south, north and west Scotland and became conservator of forests for west Scotland, with headquarters at Glasgow, in 1946. He was transferred to the office of the Director of Forestry for Scotland in 1948, and moved to London some three years later.

New Zealand Research Award : Dr. P. Whittle

The research medal awarded by the New Zealand Association of Scientists for outstanding research work (principally in New Zealand) for those under forty years of age has been made this year to Dr. P. Whittle, of the Department of Scientific and Industrial Research, Applied Mathematics Laboratory. Dr. Whittle's work has been concentrated mainly around the theory of time series and stochastic processes, a modern development in the mathematical theory of probability which makes it possible to understand and interpret data such as economic, biological and geophysical measurements which, while they possess a certain tendency to regular changes, are so subject to random shocks that this tendency is largely obscured.

Perkin Centenary Trust Awards

The following awards for educational purposes relating to the manufacture or the application of colouring matters have been announced by the Perkin Centenary Trust: the Perkin Centenary Fellowship is to be offered for postgraduate study at a university or technical college; two Perkin Centenary Scholarships will be offered to enable candidates employed in the appropriate industries to receive an education at a university or technical college. Two Perkin Exchange Lectureships are also to be created. The first, of short term, is intended to enable a senior teacher at a university, or technical college, to visit some similar establishment overseas in order to deliver a short course of lectures. In return, a visit to a British institution by some overseas scientist will be arranged. The second appointment contemplated will permit a similar exchange of lecturers for a period of up to one year.

The Perkin Centenary Trust was established in January 1956 to administer the funds subscribed to commemorate the discovery of the first synthetic dyestuff by Sir William Perkin in 1856. The secretary to the Trustees is Mr. J. R. Ruck Keene, to whom inquiries should be addressed, at the Chemical Society, Burlington House, London, W.1.

Further Education in Science and Technology in Britain

In a written answer in the House of Commons on December 12, the Minister of Education, Sir David Eccles, gave the number of full-time day students studying engineering in establishments of further education in England and Wales in 1954–55 as 7,455, compared with 6,944 in 1953–54; of these, 1,355 were on sandwich courses (compared with 746 in 1953–54), and there were 146,221 part-time day students (131,376 in 1953–54). For science the figures were 3,173 in 1954–55 and 3,526 in 1953–54, of whom 71 and 69 were on sandwich courses, and 11,010 part-time day students (10,791 in 1953–54). Enrolments in evening classes in mathematics and natural sciences totalled 429,282 in 1954–55 and 410,400 in 1953–54; for engineering and allied industries the corresponding figures are 278,466 and 269,564. In grant-aided establishments of further education 1,209 full-time and 1,128 part-time day students of engineering were recorded as studying for university degrees in 1954–55, 2,229 full-time and 68,115 part-time for National Certificates; 185 full-time and 43,184 part-time for City and Guilds examinations and 2,199 full-time and 3,454 part-time for other examinations. For science the corresponding figures are 2,279 full-time and 5,184 part-time day students for university degrees; 74 full-time and 10,829 part-time for National Certificates; 444 part-time for City and Guilds examinations; and 1,298 full-time and 4,262 part-time for other examinations.

Technological Education in France

The Paris Academy of Sciences, supporting proposals made by the Association des Professeurs de Mathématiques, the Union des Physiciens and the Union des Naturalistes, has submitted to the French Government a resolution in favour of certain reforms in scientific education (*C.R. Acad. Sci., Paris*, 243, 1811; 1956). The Academy, disturbed by the grave situation created by the growing shortage of scientists, engineers and technologists, and the inadequate number of young men embarking on a scientific career, points out the necessity for recruiting not only men with a vocation for the abstract sciences and mathematics, but also those with an aptitude for observation and experiment. The Academy therefore proposes that, in order to satisfy this dual requirement, matriculation examinations should not be such as to discourage from scientific careers young men not especially gifted in mathematics. It is also proposed that secondary schools should be less concerned with detailed instruction than with laying a firm foundation of basic principles; and that every effort be made to attract pupils to science by introducing them at an early age to the experimental method, by practical exercises and characteristic examples, to be reinforced at a later stage by more predominantly scientific instruction. Finally, it is proposed that every initiative be encouraged toward recruiting competent teachers even without diploma, and accepting students even without competitive examination, in view of the urgency of the need.

Imperial College of Science and Technology, 1954–55

The forty-eighth annual report of the Governing Body of the Imperial College of Science and Technology (London) for the year 1954–55 (from the College) notes that appointments were made to the new chairs of applied science, with special reference to engineering, soil mechanics, heavy electrical engineering, physical chemistry, instrument technology, statistics, parasitology, applied geophysics and aeronautical structures, and to readerships in applied geochemistry, physical chemistry, mining and chemical engineering. A strong expansion committee has been appointed from among members of the Governing Body, and the physical expansion of the College is gathering momentum. An additional story over the Goldsmiths' Company Extension to the City and Guilds College and the Royal School of Mines was completed in April 1955 and, besides relieving congestion due to the increased intake of engineering students, provides new accommodation for applied geophysics and applied geochemistry. A further extension of chemical engineering in connexion with a new aeronautics building was scheduled for occupation by the latter in October 1956, and by chemical engineering in December 1956. Rebuilding of the Imperial College Union was expected to be complete in September 1956, and an alteration in the Bessemer Laboratory of the Royal School of Mines to serve as a temporary house for the Mechanical Engineering Workshop and Materials Laboratory is already complete. Two stories are also being added to the single-story part of the Chemistry Department. These beginnings have all been made on sites already in possession of the College, and any further expansion by building awaits acqusition by the College of other parts of the 'island site' at present occupied by other institutions. Details of staff changes are appended to the report together with a list of publications and brief notes on departmental research. Of the 2,282 students (including 412 part-time) in 1954–55, 1,840 were from the United Kingdom, 256 from the British Commonwealth and 186 from other parts of the world. Of the total, 1,019 were postgraduate, 229 were from London and 870 from the Home Counties.

Atom

Atom, the monthly bulletin of the United Kingdom Atomic Energy Authority, is distributed to the staff of the Authority, to similar organizations overseas, to industrial firms concerned with the exploitation of nuclear energy, to the Press and to those to whom a record of information on the work of the Authority may be useful. The first issue (November), consisting of twenty-four pages, contains a report of the events of October 17, when Her Majesty Queen Elizabeth II pressed the switch that allowed power from the Calder Hall nuclear power station to pass into the national grid. The report includes the Queen's speech and technical details of Calder 'A' station. Apart from short notes dealing with diamond irradiation, the new reactor school at Harwell, and LIDO, and abstracts of patents, the main contents are devoted to the addresses given by Sir Edwin Plowden and Sir John Cockcroft at the meeting of the International Bank for Reconstruction and Development held on September 27. Sir Edwin spoke on the development of the nuclear power programme in Britain and compared British plans with likely trends of development in other countries. Sir John referred to the economic background against which the United Kingdom programme is progressing and undertook in his speech the speculative and difficult task of looking five or ten years beyond the United Kingdom programme as planned until 1960. He concluded by stating that "it is certain that, with the great power of creative technology to-day, development will be rapid and capital costs of nuclear power projects will fall rapidly. In spite of this, I think it will be a long time before nuclear power is competitive with 4-mill hydroelectric power".

Limiting Atomic War

A PAMPHLET, "On Limiting Atomic War", issued by the Royal Institute of International Affairs (London, 1956; 2s. 6d. net), is the outcome of discussions on the problems of defence policy in the nuclear age between Rear Admiral Sir Anthony Buzzard, Prof. P. M. S. Blackett, Denis Healey, M.P., and Richard Goold-Adams in the summer of 1956. It puts the arguments in favour of trying to draw distinctions between the tactical and strategic use of atomic weapons. Written by Richard Goold-Adams, it presents the case for graduated deterrents, arguing that if a start were made now, distinctions between tactical and strategic nuclear weapons would be both desirable and practicable; that it is similarly possible to draw a line between tactical and strategic targets; and that the area of almost any future war outside Western Europe could be limited. The argument turns on the facts, first, that it is only a relatively recent trend, confined almost entirely to this century, that major war should tend to spread into world war; and secondly, that it is only in world war that the generals are able to dominate the politicians. If, however, it is disputed that distinctions between big and little nuclear wars are practicable, the present costly policy of developing large quantities of small-scale nuclear weapons is already wrong. The time has already passed when any British government can afford not to find out whether the argument in this pamphlet is right or wrong. Until it does so it has no clear line of defence policy around which to rally public opinion and may continue to spend resources, which our economy can ill afford, on tactical nuclear equipment which will be largely wasted and provide no proper defence shield in return.

Oil Flax Seed

THE spectacular rise in fibre flax cultivation and the consequent increased demand for sowing seed during times of national emergency are common knowledge in the United Kingdom. The trend of cultivation of oil flax in the countries of northern Europe seem to follow a somewhat similar pattern. During and for some little time after the Second World War, when oil flax was being grown on a large scale in Sweden, a programme of research designed to improve the seed yield of this crop was undertaken at the Plant Breeding Station, Gullåkers, by Rolf Manner. The results of Manner's work, which has now been concluded, are published in monograph form entitled "Studies on Seed-setting and Seed Yield in Oil Flax" (Meddelande från Gullåkers Växtförädlingsanstalt, No. 12. Hammenhög: Gullåkers Växtförädlingsanstalt, 1956). In the course of a thorough and detailed study of the problem, the author has investigated intra-plant variability, the influence of environmental conditions and the genetical variation in seed-setting and seed yield. After remarking that increased seed production may be effected by a changed environment such as would be brought about by increased manuring (nitrogen and potassium) and plant husbandry and suggesting that such improvements may be immediately utilized, he points out that improvements in other ways and, in particular, by plant breeding must be exploited in full. The breeding work which he undertook indicates that even greater progress can be achieved in this way than by the provision of changed environmental conditions. The question of heterosis in flax breeding is examined in some detail, and the possibilities of obtaining increased yield by sowing F_2 seed are believed to be very real, although it is admitted that many problems remain to be solved before this becomes a practical possibility. The monograph contains an excellent review of foregoing literature and the publication has been ably translated by C. Montagu Evans. It is pleasing to note that the author hopes, in spite of the fact that much of the work may not assume importance under Scandinavian conditions, that he has been able to contribute some results which may be applicable beyond the frontiers of northern Europe. It is a monograph which will be welcomed by all who are interested in the problems of flax breeding.

Dedication of Woodlands in Great Britain

THE fourth edition of the Forestry Commission pamphlet, entitled "The Dedication of Woodlands: Principles and Procedures" (Booklet No. 2: pp. 60. London: H.M.S.O., 1956; 2s. 6d. net), has been issued with a foreword by Lord Radnor, chairman of the Forestry Commission, and Major Sir R. Proby, chairman of the United Kingdom Forestry Committee. The dedication scheme was first introduced in 1948, with the object of assisting in the replanting and proper maintenance of privately owned woodlands, and it is for this assistance that it is recommended to all owners who have not yet come into the scheme. Steady progress has been made since its introduction. By September 30, 1955, the total area covered by completed dedication deeds was 410,000 acres, with another forty thousand acres in preparation. Owners who have had several years of the working of the scheme say that in practice it allows them greater freedom than before. A plan of operations, drawn up by the owner himself, is helpful in dealing with the management problems. In the early stages after dedication, Forestry Commission officers pay visits and assist with advice. These visits are helpful; but they are made with the knowledge that both the responsibility for them and management of the woods remain with the owner and that any rigidity in working the plan will defeat the objects aimed at. The pamphlet gives a full description of the dedication scheme with examples of the deed covenant for England and Wales, and a separate one for Scotland

Nitrogen and Root Metabolism

IN further studies of the respiration of barley plants, E. W. Yemm and A. J. Willis (*New Phytol.*, 55, 2, 229; 1956) have investigated the nature of the products formed during the assimilation of inorganic forms of nitrogen by excised roots. Some new analytical methods are described. They have observed that under all conditions of rapid assimilation there is a marked increase of glutamine, and the experiments with nitrogen-15 show that glutamine arises as a result of primary synthesis. When ammonium salts are supplied, more than 80 per cent of the nitrogen metabolized during the initial period of rapid assimilation can be recovered as glutamine. With nitrate, somewhat smaller quantities of glutamine are formed, together with asparagine and amino-acids. The data from experiments with different sources of nitrogen are consistent with the view that nitrate is converted to nitrite and hydroxylamine, and there is evidence that the step from nitrate to nitrite is relatively slow. The synthesis of amino-acids and amides is closely associated with high rates of respiration and rapid losses of carbohydrates from the tissues. Evidence is presented that both the carbon skeleton of the amides and the respiratory carbon dioxide result from the breakdown of carbohydrate. The regulatory mechanisms which may operate during the assimilation of different forms of nitrogen are discussed. No marked increase of tissue proteins occurs in the excised roots ; but an extensive incorporation of nitrogen-15 into these proteins could be detected. There is no evidence that the operation of a continuous protein cycle plays an important part in regulating the rate of respiration in these roots.

Zoological Nomenclature

THE International Commission on Zoological Nomenclature will start voting as from March 28, 1957, on the following cases involving the possible use of its plenary powers ; full details have already been published (*Bull. Zoo. Nom.*, 12, Pt. 9 ; September 1956) : (1) Rafinesque, 1814–1818, names published by, for genera and species in the orders Decapoda and Stomatopoda (cl. Crustacea), suppression ; (2) *cruentatus* Linnaeus, 1758, *cubicus* Forskål, 1775, and *novemdecos* Sulzer, 1776, all published in combination with the generic name *Cancer* (cl. Crustacea, order Decapoda), suppression ; (3) Urinatoridae Vieillot, 1818, suppression of, in favour of Gaviidae Coues, 1903 (cl. Aves) ; (4) *Peltura* (emend. of *Peltoura*) Milne Edwards (H.), 1840 (cl. Trilobita), validation. Comments should be sent as soon as possible to Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

Insecticidal Effect of Nigerian Diatomite

COMPARATIVE tests have been made by E. A. Parkin and Enid I. C. Scott, of the Pest Infestation Laboratory of the Department of Scientific and Industrial Research, and E. R. Varley, of the Mineral Resources Division of the Colonial Geological Surveys, on the insecticidal efficiency of a colloidal silica preparation and several particle-size fractions of a Nigerian diatomite to assess the potentiality of the latter for local use in the protection of infestable stored produce (*Col. Plant and Animal Prod.*, 5, No. 3 ; 1956). The tests were made with *Calandra granaria*, *C. oryzae* and *Tribolium castaneum*. The finest fraction of the diatomite had a good insecticidal effect at 25° C. and 70 per cent relative humidity when used as a dry dust, although it was not so effective as the colloidal silica. However, when applied as an aqueous suspension to bricks, the dry deposit of colloidal silica was insecticidally efficient, whereas that of the diatomite failed completely because of caking. It would have been particularly advantageous in the groundnut storage areas of Northern Nigeria if the diatomite could have been used in aqueous suspension to avoid excessive losses during application of dry dusts in the local high winds.

Electron Physics Tables

THE National Bureau of Standards, Washington, D.C., has recently prepared "Electron Physics Tables" (Circular No. 571 ; pp. 83. Washington : Government Printing Office, 1956 ; 50 cents), which replace the out-of-print and partly obsolete tables published in 1941 as Part 2 of "Miscellaneous Physical Tables. Planck's Radiation Functions and Electron Functions. U.S. National Bureau of Standards. Mathematical Tables 17". The calculation of the tables was carried out on the Bureau's automatic digital computer, SEAC, and the eight tabulated quantities, each given to eight significant figures, are : the potential difference in absolute volts required to impart a kinetic energy E expressed in electron volts to an electron initially at rest ; the effective relativistic potential difference ; the product of magnetic field strength in œrsteds and the radius of curvature of electron path in centimetres ; the de Broglie wave-length of the electron ; the momentum of the electron measured in units of m_0c, where m_0 is the rest mass of the electron and c is the velocity of light ; the kinetic energy of the electron measured in units of its rest mass energy, m_0c^2 ; the total energy of the electron measured in units of the rest energy ; and the ratio of the electron velocity to the velocity of light. The electron energies quoted range from 0·206 eV. to $3 \cdot 353 \times 10^{12}$ eV. The values of the fundamental constants adopted in the computation of the tables are those given by J. W. M. Dumond and E. R Cohen (*Rev. Mod. Phys.*, 25, 691 ; 1953).

Photometric Theory of Lunar Eclipses

THE sixteen lunar eclipses between October 16, 1921, and July 15, 1954, are discussed by F. Link in a paper, written in Czech but with an English summary, entitled "Catalogue of Eclipses of the Moon, 1921–1954. 2 : Measurements of the Density of the Shadow" (Pub. Č 29, Nak. Česk. Akad. Věd, Praha ; 1956). In 1933, Link had established a photometric theory of lunar eclipses, based on contemporary knowledge of the terrestrial atmosphere and directed specially to the exploration of the upper atmosphere (*C.R. Acad. Sci., Paris*, 196, 251 (1933), and *Bull. Astron.*, 8, 77 (1933)). Since then the numerical results of his theory have served for comparison with measurements of the density of the Earth's shadow, and the object of the present paper is to give a summary of these comparisons in view of a proposed revision of the earlier theory. Many precautions are necessary in measuring the density of the terrestrial shadow thrown on the Moon, and certain disturbing factors intervene—in particular, the light scattered in the instrument used for the measurements or in the Earth's atmosphere, and then the atmospheric absorption and its variations, which are all likely to vitiate considerably the measurements. Fortunately, the photometer described by A. Danjon (*Ann. Obs. Strasbourg*, 2, 1 ; 1928) provides results in which systematic errors are automatically eliminated. There is now a long series of measurements of this nature which were made between 1921 and 1954, and the work under consideration contains the results of this series. In addition to sixteen pages of tabular matter showing the densities of the shadows, there are sixteen curves—one for each eclipse—showing the densities as functions of the angular distance from the centre of the shadow, and other curves and diagrams supplying additional information. A detailed discussion has been reserved for the future, but the following provisional deductions have been made. In the shadow and in the green and red parts of the spectrum, there is normally a deficiency of light with regard to the Rayleigh atmosphere, but in the blue—and in exceptional circumstances in the green and red—there is an excess of light with reference to the Rayleigh atmosphere. In that part of the penumbra which is close to the geometrical limit of the umbra, there is often an excess of light which is difficult to explain by any known phenomena. In both the umbra and the penumbra there is often a marked dissymmetry between the increasing and decreasing phase, and it is suggested that the above facts should serve as a starting-point in the future for revising existing theories of lunar eclipses.

Bibliography of Seismology

No. 15 of the valuable "Bibliography of Seismology" (Vol. 14 in "Publications of the Dominion Observatory, Ottawa"), edited by W. E. T. Smith and covering the period January–June 1954 (Items 8547–8772), includes 326 items in pure and applied seismology, culled from some twenty countries and taken from seventy-seven journals. Particularly interesting is the present use of explosions employing very large masses of explosive, in order to determine deep-crustal structure. Such experiments by H. Reich and O. Fortsch in southern Germany (Items 8600, 8703 and 8704), by a group of seismologists in Japan (Items 8705, 8706), and by H. E. Tatel, L. H. Adams and M. A. Tuve in the United States (Item 8746) are listed. The work of M. N. Hill and A. S. Laughton on seismic observations (using explosives) in the eastern Atlantic and of M. Hayakawa and K. Mori on seismic prospecting on the sea bottom near Sakito, Nagasaki Prefecture, are noted.

University of Birmingham

The following appointments have been made in the University of Birmingham: J. W. Glen, to be lecturer in physics; C. R. Patrick and G. H. Whitham, to be lecturers in chemistry.

The Huxley Lecture will be delivered on March 7 by Prof. C. D. Darlington, Sherardian professor of botany in the University of Oxford.

The Sir Josiah Mason Lectures will be delivered in the session 1957–58 by Sir Solly Zuckerman, Sands Cox professor of anatomy and director of the Department of Anatomy in the University; the lectures are to be entitled "Control of Population Growth".

The Night Sky in January

New moon occurs on Jan. 1d. 02h. 13m., U.T., full moon on Jan. 16d. 06h. 21m. and new moon on Jan. 30d. 21h. 24m. The following conjunctions with the Moon take place: Jan. 9d. 09h., Mars 3° S.; Jan. 20d. 20h., Jupiter 6° N.; Jan. 26d. 00h., Saturn 0·4° N.; Jan. 28d. 16h., Mercury 2° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Venus on Jan. 21d. 16h., Mercury being 2·8° N. Mercury is unfavourably placed for observation. Venus is a morning star, visible very low in the south-east just before sunrise. Mars sets at 0h. 35m., 0h. 30m. and 0h. 20m. on January 1, 15 and 31, respectively; its stellar magnitude decreases during the month from + 0·3 to + 0·9, its distance from the Earth increasing from 98 to 124 million miles. Mars continues to move eastwards, being near δ Piscium at the beginning of the month, and passing into Aries on January 27. Jupiter rises at 23h. 20m., 22h. 30m. and 21h. 20m. at the beginning, middle and end of the month, respectively, and is near η Virginis; its stellar magnitude is about – 1·7, its distance in the middle of the month being 460 million miles. Jupiter is stationary in right ascension on January 17, and subsequently begins to move westward among the stars. Saturn is now in Ophiuchus, and rises at 5h. 40m., 4h. 50m. and 3h. 50m. on January 1, 15 and 31, respectively; its stellar magnitude is + 0·7 and its distance from the Earth is approximately 1,000 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Jan. 17d. 20h. 53·9m., ω Leo. *m* (*R*); Jan. 22d. 6h. 27·5m., 68 Vir. (*R*). *R* refers to reappearance. The Quadrantid meteors will be active on January 3, but maximum activity is expected during daylight and conditions for observation are not favourable. The Earth is in perihelion on January 3, its distance from the Sun being 91·3 million miles.

Announcements

Dr. Albert Parker, director of fuel research in the Department of Scientific and Industrial Research since 1943, is retiring on December 31, after twenty-eight years service with the Department. Dr. A. C. Monkhouse, at present deputy director, has been appointed acting director of fuel research.

Dr. W. M. Elsasser, formerly professor of theoretical physics at the University of Utah, has joined the staff of the University of California, Scripps Institution of Oceanography, as research physicist.

The Children's Lecture of the Manchester Federation of Scientific Societies will be given by Prof. C. E. H. Bawn in the Chemistry Lecture Theatre in the University, Oxford Road, Manchester, on January 3 and 4 at 3 p.m.; Prof. Bawn will speak on "Progress of Plastics". Admission is by ticket from one of the societies comprising the Manchester Federation.

A principal theme of the national sectional meetings of the National Union of Teachers to be held at the Friends House, London, N.W.1, during January 2–4 will be "The Place of Mathematics and Science in the Curriculum at all Stages of Education". Dr. J. Bronowski is opening the proceedings with a paper on "The Purpose of a Scientific Education". The teaching of mathematics at various ages and the expansion of technical education will be discussed at other sectional meetings being held at Church House, Caxton Hall and the Institute of Education (University of London).

The second International Congress of Surface Activity will be held in London during April 8–12, with Lord Brabazon of Tara as the president of honour and Sir Eric Rideal as the president. Membership of the Congress is open to all on payment of a fee of £4. Inquiries should be addressed to the Honorary Secretary, Second International Congress of Surface Activity, 14 Belgrave Square, London, S.W.1.

The Bradford Chemical Society, in conjunction with the Department of Chemistry and Dyeing of the Technical College, Bradford, and the Yorkshire Council for Further Education, is to hold a symposium on "Recent Developments in the Chemistry of Fibrous Linear Polymers" at the Technical College on February 15 and 16, 1957. There will also be an exhibition of chemical apparatus and of fibres and fabrics. There is no fee for attendance at either lectures or exhibitions, but inquiries about either may be addressed to Dr. W. R. Moore, Department of Chemistry and Dyeing, Technical College, Bradford.

HIGH-SPEED PHOTOGRAPHY

THERE has been an increasing interest in the techniques of high-speed photography and in their application. In October 1952 the Society of Motion Picture and Television Engineers of New York organized an International Congress on High-Speed Photography and held it in conjunction with its annual meeting in Washington. The number of people who attended and the extent of the interest were such that it was decided to hold other meetings, the next in Europe. The Second International Congress on High-Speed Photography was held under the auspices of the Association Française des Ingénieurs et Techniciens du Cinema in Paris in September 1954. A great deal of material was submitted to this Congress and has been published recently*. These proceedings are an impressive indication of the breadth of the subject and of the extent of its applications. Sixty-eight papers were presented, and the proceedings are extensively illustrated, by some 650 illustrations, many of which include a number of separate pictures, so that the whole number of illustrations runs into the thousands.

As many major advances have been made in Britain, it was decided to hold the next Congress here. The Department of Scientific and Industrial Research agreed to sponsor the Congress, which was held in London during September. It is a measure of the extent to which the Congress was truly international that of the 330 members who attended, ninety-six were from overseas, representing fourteen different countries.

The papers for presentation were submitted to the editorial committee some months before the Congress. There was severe restriction of the length of the papers and of the numbers that could be accepted. Papers describing work which had been published elsewhere were automatically rejected. This strict editorial policy meant that papers presented and to be published in the proceedings are of a high standard, and describe new and original techniques and applications that are nowhere else available in the published technical literature. The papers were all preprinted and copies made available to members before the opening of the Congress. They were therefore not read *in extenso*, but each author gave a résumé of his work and indicated what advances there had been in recent months. Ample time was thus left for discussion and comment on each of the papers. One of the most valuable features of the whole Congress was the vigour of the discussion and the attention that could be given to individual problems, inquiries and suggestions. Summaries of the discussions will be included with the proceedings.

The main topics discussed at the different sessions of the Congress are indicated briefly below.

Flash light sources. There were considerable advances in the detailed study of sources and in the efficiency of conversion of energy for single-shot work (E. P. Tawil; D. P. C. Thackeray; M. Laporte; J. S. T. Looms and R. J. North; P. Devaux; I. S. Marshak); and in the development of equipment that could produce a series of short flashes at high rates (H. E. Edgerton; F. Früngel). Valuable work was also reported on the production of rectangular pulses of light suitable for illuminating an event while a whole sequence of pictures was taken (D. P. C. Thackeray). Analyses were also presented of the light source requirements, and how these could be met, for work in wind tunnels (L. H. Tanner; J. S. T. Looms and R. J. North).

Image-splitting and image-dissection techniques. New techniques were described which allow fast photography through a microscope with very simple equipment (J. S. Courtney-Pratt and D. P. C. Thackeray; J. S. Courtney-Pratt). A combination of image-converter and image-dissection techniques was described which allows a high throughput of light and which has already been used to take a sequence of fifty pictures at a rate of 5×10^7/sec. (G. H. Lunn). This technique is likely to be of far-reaching importance as already it gives very high rates and yet is nowhere near the limit to which it can be pressed. Further development work will be required but should be amply repaid, as fundamental limitations are unlikely to be restrictive for speeds higher still by a factor of 100 or 1,000.

Inertialess shutters. The use was described of image converters for taking single-shot pictures with an exposure of 3×10^{-9} sec. (R. F. Saxe), and an assessment presented of the efficiency of present-day converters and the extent to which their efficiency may be increased (R. A. Chippendale). It would seem that one may hope eventually to get an intensification of the image by a factor of 100 or so. Advances in the use of Kerr cells were described, and a valuable new method of switching the light beam from one path to another so that a short series of pictures can be taken at speeds up to the maximum operating speed of these switching cells (E. W. Walker). A combination of image dissection and Kerr cell aperture-scanning was described (J. L. Viard). As in this equipment the Kerr cells are of very small dimensions, the equipment can give a qualitative study of an event at even higher rates.

Applications in industry and biology. Two papers were presented on machine and combustion analysis (R. O. Painter; J. G. G. Hempson), and a paper was presented describing a study of the flow of blood corpuscles *in vivo* (A. M. P. Brookes and P. A. G. Monro). This paper described new techniques of much wider application than simply to the particular project for which they had been developed. A cathode-ray tube was used as a repetitive source, and it was shown that one could estimate the velocity of mean flow of a stream in which randomly distributed particles are transported, by a method similar to the stroboscopic study of consistently repetitive events. The authors likened the pattern that could be seen to raindrops on a windscreen. The pattern would show no drift if the frequency of flash was equal to the mean rate of passage of particles.

Application to ballistics and explosives. A large proportion of the development and use of high-speed photography has always been in the military field. A number of papers were presented in this and other sessions that described cameras developed for use in guided-weapon trials (R. Herden; P. B. N. Nuttall-Smith), in supersonic flight (J. S. Rinehart), in proof-range work (R. Herden; M. B. Prudence; J. H.

---

* "Actes de 2e Congrès International de Photographie et Cinématographie Ultra-rapides" (Dunod, Paris, 1956).

Waddell; M. Sultanoff; T. Uyemura and T. Morishige; P. Devaux; J. S. Rinehart; J. L. Viard; E. W. Walker; H. F. Hills; T. Uyemura; L. Zernow and G. E. Hauver), and in studies of safety hazards of the ignition of explosives and of gas mixtures (A. Berthmann and H. Käufer; M. Giltaire).

Instrument aids. Two papers were presented on more precise time measurement (P. Fayolle; W. Baur and K. Pfister), and a camera was described with a system that allowed the separation of pictures taken with different colour pass-bands (R. L. Aspden). A number of authors pointed out that similar means could be used to increase the framing rate, to increase the number of pictures in a sequence, or to differentiate between different features of an event (J. S. Courtney-Pratt and D. P. C. Thackeray; N. Dombrowski; W. D. Chesterman). A paper was presented in this session which described a method for studying the fracture process within a solid (F. Kerkhof). In the simplest case of brittle failure in tension, a straight fracture front will generate a plane fracture surface in a solid. If ultrasonic waves are present, the instantaneous direction of movement of the fracture front can be a little affected. After fracture, the ripples in the surface show how far the fracture front had advanced between successive maxima of the ultrasonic wave. This is a powerful method, as it allows one to study the shape and movement of a fracture front inside even an opaque material, whereas the ordinary photographic methods are restricted to a study of the movement of the crack at the surface.

Photographic materials. A number of papers were presented on the behaviour of ordinary and colour emulsions, with reference particularly to their behaviour at short exposure (R. J. North and N. A. North; J. Eggert and R. von Wartburg; R. von Wartburg; J. Castle, W. Woodbury and W. A. Shelton). Many emulsions show reciprocity failure by a factor of 2 or 3 for exposures between 10^{-3} and 10^{-5} sec. It used to be thought that there might be even greater reciprocity failure at shorter times still; but most of the evidence produced at this Congress indicates that the sensitivity of the emulsions is not much further reduced for exposure times as short even as 10^{-9} sec. (H. Hoerlin).

X-rays. Papers were presented on ciné-radiography of biological subjects at rates up to 125 frames per sec. (S. A. Weinberg, J. S. Watson and G. H. Ramsey), and on a study of the movement of shock waves in solids by the use of flash X-ray bursts of duration between 10^{-6} and 10^{-7} sec. (R. Schall). There was also a valuable paper describing a critical study of the role and influence of gas in X-ray tubes (R. F. Thumwood). It was shown that the efficiency could be greatly increased by controlling the pressure of gas with an optimum at pressures in the range 10^{-3} to 10^{-4} mm. mercury.

Film evaluation. Papers were presented describing methods of reading films, and of data processing (B. S. Benson; W. N. McJilton; J. Rieck). This is a problem of growing importance, as with the increase in speed the number of frames to be measured has made this the most laborious operation of the whole investigation; so much so that considerable increase in the complexity of recording equipment is amply justified if it can lead to a more direct means of assessment.

Optical techniques. Contributions were made describing installations that made use of the Cranz–Schardin system, of interferometric and schlieren techniques (H. F. Hills; H. Schardin; J. Dyson), and of an optical system that combined some of the advantages of phase-contrast and schlieren systems (R. Bouyer and C. Chartier). There was also an elegant new method described for extending the range of schlieren systems utilizing the moiré patterns that can be obtained by the use of two separated grids (T. Fromme).

Rotating mirror cameras. Several new cameras were described (B. Brixner; A. E. Huston; T. Uyemura; L. Zernow and G. E. Hauver; J. Tchernyi), and there was a vigorous discussion of the limitations of such systems from considerations on one hand of diffraction limits and the ultimate strength of materials, and on the other by the technical difficulties of manufacture of components of sufficient quality. Prof. H. Schardin showed that for rotating-mirror framing cameras and streak cameras the product of the framing-rate and the number of lines resolved across the frame in the direction of movement of the image could not with present materials be made higher than 4 × 10^{9} sec.$^{-1}$. One thus has a valuable criterion for assessing the performance of a camera by seeing how nearly this limit is approached. It became evident from the discussion that one might considerably surpass this limit if one took advantage of the principles of image dissection or the increased sweep-rate with image-converter cameras, and might well go even further by combinations of dissection and image converters.

Medium repetition-rate cameras. Cameras were described that showed considerable advances in resolution, and consistency of operation even under adverse conditions (B. W. Allwood, J. R. Bouffler, B. B. E. Death and D. Jones; J. H. Waddell; R. Herden; P. B. N. Nuttall-Smith); and also a system that allowed rapid acceleration of a loop of film to avoid the long delay and film wastage that often occurs in more conventional equipment (M. B. Prudence).

Applications to fluid dynamics. Papers were presented describing installations for studying flow in wind tunnels and in water (H. P. Liepman and J. B. Cooper; F. Früngel, E. Baillitis and W. Thorwart), in shock tubes (H. Schardin), and water entry tanks (E. G. Richardson). Methods were described for studying droplet formation (J. G. A. de Graaf; R. P. Fraser and N. Dombrowski) and jet disintegration (Y. Kumano). An interesting series of pictures was presented which showed the extraordinary differences in the detail that were visible with different methods of illumination (R. P. Fraser and N. Dombrowski). This was a salutary reminder that one must not assume that things are not there if they cannot be seen on a photograph. Attention to the details of the technique can perhaps make them evident.

Review papers. Colonel P. Naslin opened the technical sessions of the Congress by presenting a paper on the state of the art. As his main topic he drew an analogy between the practices and principles of high-speed photography on one hand, and the developments in control and information theory on the other. One may record continuously the variation of amplitude of one or another of the parameters, or one may sample the value of a number of parameters at a given instant (as in ordinary intermittent-movement ciné cameras). One may, however, sample in other dimensions, and dissection systems are typical of this. One might also sample, quantize, code, or multiplex other variables, so that one could raise to the maximum the rate of recording of those features of the incoming information that are most relevant. A consideration, then, of the similar advances in communication theory can stimulate advances in the whole field of high-speed photography.

A review of the work of the Congress was presented on the last day (J. S. Courtney-Pratt). Advances in particular techniques were commented upon. Trends of design were indicated. A summary was given of the emergence of principles of assessment with emphasis on the contributions, mentioned above, of Colonel Naslin and Prof. Schardin.

An exhibition was held in conjunction with the Congress, and a review has been prepared by A. R. Michaelis. This was by far the most comprehensive display of equipment for use in high-speed photography that has ever been held in Britain, and included exhibits from commercial firms, from government departments, and from universities, ranging from equipment that could be bought 'off the shelf' to research equipment that is in the process of development. It was significant that equipment that was described for the first time at the Congress in Paris is now in use at a number of laboratories and was on display at this Exhibition.

The published Proceedings of the Congress, including the review papers and summaries of the discussion and a brief description of the Exhibition, will be available from Butterworths Scientific Publications, London, in January 1957.

At the Congress the range of topics covered indicates the growth and breadth of the subject. Photographic methods are among the most powerful of the tools we have. The study even of processes we think of as slow requires short exposures and high repetition-rates when the interest is in the fine detail; and more and more we must rely on the techniques of high-speed photography. For studies on the microscopic scale the problem is accentuated, and we must take advantage of the most advanced and elaborate of the new techniques, and also must apply research and development effort to the improvement of these techniques. The ever wider use of high-speed photography in research and industry is a foregone conclusion, and it is as certain, too, that this will contribute to more rapid progress in science and technology.

J. S. COURTNEY-PRATT

THEORETICAL CONSIDERATIONS ON GRINDING

A SYMPOSIUM consisting of five papers on various aspects of grinding was held by the Institution of Chemical Engineers at the Royal Institution on November 7, under the chairmanship of Mr. A. S. White.

The first paper, by Dr. H. E. Rose (King's College, London), dealt with an attempt to predict the principal features of ball-mill behaviour from purely theoretical considerations. The basis of the method is to use suitable probability functions to compute the probability of a particle entering a 'zone of operation' around a contact point between a pair of balls and to compute the probability of occurrence of some process after the particle has entered this 'zone'.

From this reasoning it is possible to predict a number of features of ball-mill performance which, although they have been observed in practice, have not, so far as is known, been predicted theoretically. From such considerations it was suggested that, in certain circumstances, the ball-wear may be reduced by the use of softer metal; that the rate of grinding may be increased by the use of a reduced powder charge in the mill, although this can only be accomplished at the expense of increased rate of metal wear; and that the relationship between the surface produced and the time of milling is a function of the relative hardness of the balls and the material being ground.

A second paper by Dr. Rose was an attempt to analyse the performance of a vibration mill, by the application of the method of dimensional analysis; the justification of this paper being that the vibration mill appears to offer the possibility of very rapid milling of certain classes of materials which are otherwise difficult to pulverize.

The treatment has led to the conclusion that the rate of grinding in a vibration mill varies as a fairly high power of the frequency and of the amplitude of the vibration; furthermore, the exact relationship between the rate of grinding and the frequency and amplitude depends upon whether the energy to produce new surface or the limiting stress in the particle is the criterion for comminution.

By analysis of the published data, it was shown that the rate of grinding is proportional to the density of the ball material, and that the maximum rate of grinding is achieved when the powder in the mill is just sufficient to fill the space between the balls.

A paper dealing with the application of the principle of similarity to mills and to the grinding process was presented by Prof. A. H. M. Andreasen (Royal Technical University, Copenhagen).

In this paper it was shown that geometrically similar jaw crushers, cone crushers and similar machines, in which the stressing of the particle is brought about by mechanical means, will operate at the same efficiency regardless of size, but the throughput will vary as the cube of the size. For edge-runner mills, however, in which the stressing of the particle arises from gravitational forces, the throughput and energy consumption both vary as the square of the linear dimensions when the peripheral speed is constant; and as the cube of the size when the speed of rotation is fixed. With hammer mills, the condition for similarity is that the peripheral velocities must be constant irrespective of size and, under this condition, the production will vary as the square of the size of the mill.

For mills in which the inertial forces are produced by gravity, for example, the ball mill, the condition for similarity is that the densities of the grinding media shall vary inversely as the scale ratio of the machines. Since such materials are not available, true similarity cannot be maintained, and this is probably the reason why very small ball mills are not usually very successful.

When dealing with the principle of similarity applied to the crushing process, Prof. Andreasen showed that his experiments gave rise to orthogonally affine undersize curves for the product and, furthermore, it was shown that such curves would be predicted from an analysis of the fracture pattern obtained when solid bodies are crushed in a press.

From the results of experiments and considerations of similarity, it was shown that the expression $E = C \ln F_A/F_0$ is the relationship connecting the energy input to the particle and the increase of fineness; E being the energy expended, C is a constant depending on the material, and F_0 and F_A are the fineness before and after crushing, respectively. This expression is, of course, identical with that usually known as 'Kick's Law'; but Prof. Andreasen suggested that the theoretical basis of the expression is not sufficiently well established to justify its designation as a 'law'.

In the fourth paper, Mr. J. A. Holmes (Atomic Energy Research Establishment, Harwell) introduced a new law of comminution based upon a modification of Kick's Law. As a basis for this work, Mr. Holmes explained that materials which are milled commercially are rarely homogeneous and that, since in such materials the forces resisting disruption of the particle range from weak van der Waals forces to strong chemical bonds, the strength of a particle will depend upon the type of forces operative; the strong chemical bond being operative in the small particles, whereas van der Waals forces hold the particles together in a heterogeneous material. This would suggest that a modified form of Kick's Law would be $B = kD^{1-r}$; and this in turn leads to the equation

$$W = W_i\left[1 - \left(\frac{1}{R}\right)^r\right]\left(\frac{100}{a}\right)$$

where W is the work input necessary to reduce the feed from size F to a product of size a, W_i the work input necessary to reduce material from an infinite size of feed to a product of 100 micron size, R is the reduction ratio, and r is an index which depends upon the characteristics of the material and the crushing system. When $r = \frac{1}{2}$, this equation reduces to that of Bond's third theory of comminution.

It was then shown that, for grinding tests in a ball mill, the value of the work index, W_i, as calculated by the proposed formula is more nearly independent of the size of the material undergoing grinding than is the case when the calculation is based on Bond's equation. The value of the index r, however, varies from one material to another.

The fifth paper, by Mr. J. A. Holmes and Mr. S. W. F. Patching (Atomic Energy Research Establishment, Harwell), was introduced by Mr. Holmes, who explained that it dealt with a preliminary investigation into the differential grinding of mixed minerals. It has been shown that the specific rates of reduction of the components of a mixed feed are lower when the components are ground together than when they are ground separately. The ratio of the specific rates of reduction of the two components when ground together is not, however, greatly different from that when the materials are ground separately.

Equations have been developed by means of which the circulating load of each component in a two-component mixture, undergoing grinding in a ball mill, may be computed from the total circulating load, the ratio of the specific rates of reduction of the components and their proportions in the feed.

It was suggested that a useful field of application of these equations is in the determination of the specific rates of reduction from analyses of the circulating load fractions.

When opening the discussion, Dr. H. Heywood (Imperial College, London) stated that in tests upon ball mills of various sizes he has found that the maximum rate of grinding occurs when 80–90 per cent of the space between the balls was filled with powder, this result being roughly in accord with the result deduced by Dr. Rose in his first paper. Dr. Heywood also showed that the results of recent investigations on crushing of various materials suggest that the energy necessary to produce unit increase of specific surface depends upon the energy density in free crushing and upon the type of crushing device employed.

Mr. W. F. Carey emphasized that the crushing process is complicated and cannot well be dissociated from the type of crushing plant used. In this connexion he pointed out that the new equation for crushing, developed by Mr. Holmes, gives slightly more consistent values of the work index than does that of Bond; but the new equation is based on tests on ball-mills only, whereas that of Bond was developed from tests on a wide range of crushing machinery.

Mr. Carey also suggested that experimental verification of the assumptions underlying the theory of the ball mill, developed by Dr. Rose, would be of value since, although the validity of some of the basic assumptions is open to doubt, the theory appears to lead to a number of interesting conclusions.

Mr. E. J. Pryor also emphasized that the crushing process must be studied in connexion with the type of crushing apparatus used and that, in common with those of other workers, his own experiments to deduce a law of comminution have produced results which are so complicated as to defy analysis. He showed that some of the energy supplied to a mill may be expended in bringing about chemical changes in the material being ground; examples of copper ore in which the copper compound has been changed to one having a higher energy-level at the points where the balls rub the material being shown.

It was also considered that undue claims have been made for the vibration mill, and that an accurate assessment of the potentialities of these machines is necessary.

Mr. W. C. Peck pointed out that in some applications the superiority of the vibration mill lies not in increased rates of milling over the conventional mill but in some incidental advantages. For example, in the milling of tungsten carbide, the cobalt is more evenly distributed over the particles, which leads to an improved product, while some pigments give a 'stronger' tint when so milled.

Mr. R. M. E. Sullivan said that he has carried out experiments on the crushing of glass spheres by use of a drop-hammer, and he could confirm the statement of Mr. Pryor that the results are of such complexity as to defy analysis, and also the findings of Prof. Andreasen that the product undersize curves are orthogonally affine. He is therefore of the opinion that the problem of comminution requires detailed fundamental investigation.

Mr. Sullivan also said that he has re-calculated some results of tests on a vibration mill, quoted by Bachmann, and found that they confirm the deduction, made by Dr. Rose, that the rate of milling varies as the fifth power of the frequency of vibration. This result shows that, at least for limestone, the critical stress is the criterion for comminution.

Dr. G. A. H. Elton asked whether the theory of the ball mill, proposed by Dr. Rose, would be valid for the milling of a polydisperse material composed of non-spherical particles, and, in reply, Dr. Rose pointed out that some of the theoretical conclusions are supported by published results relating to the milling of chert and dolomite, both of which are non-spherical and polydisperse, and so, at least as a first approximation, the theory appears to be applicable to such materials.

Mr. R. L. Brown showed that, by the use of matrix algebra, the performance characteristics of a closed-circuit milling installation may be deduced from the relatively simple performance characteristics of the elements of the system. Such methods, however, demand an accurate knowledge of the performance characteristics of the elements, and in this connexion accurate laws of comminution are desirable. The existence of an inter-relationship between the various elements of a mill installation at once raises the question of the extent to which the 'laws' found by experiment are dependent upon the nature of the material undergoing treatment and upon the characteristics of the plant involved.

REACTIONS AND STRUCTURE IN CARBOHYDRATES

A SYMPOSIUM on "Newer Interpretations of Reactions and Structure in Carbohydrate Chemistry" was held under the auspices of the Chemical Society on November 1, in the Chemistry Department of University College, London. There was a large and interested audience composed mostly of the younger chemists. It was a particular pleasure to note the presence of Prof. C. K. Ingold, host to the meeting, and of Prof. E. L. Hirst, president of the Chemical Society.

Dr. G. R. Barker, the organizer of the symposium, was in the chair for the afternoon session, when the opening speaker was Prof. E. J. Bourne (Royal Holloway College, London), who discussed some physical methods used in the determination of carbohydrate structures. He first outlined the contributions which infra-red analysis recently carried out in the University of Birmingham can make to the solution of many problems encountered in carbohydrate chemistry. Among the applications are the direct comparisons of unknown samples with authentic specimens, analyses of mixtures, determinations of hydrogen bonding and degrees of crystallinity, detection of substituents and of water of crystallization, etc. In suitable cases, infra-red techniques provide information on configuration, conformation, ring size, anomeric state and positions of glycosidic linkages in polysaccharides. The assignment of the more important vibrations was considered. Preliminary results in studies of the Raman spectra of ring systems in carbohydrates and their derivatives were presented. Reference was made to Dr. D. H. Whiffen's theoretical interpretation of optical activity in carbohydrates and to its possible applications in future work.

Dr. J. C. P. Schwarz (University of Edinburgh) then spoke on conformational ideas applied to tosyl esters and three-membered oxide rings. In certain carbohydrate derivatives, equatorial hydroxyl groups are tosylated more readily than axial hydroxyl groups. Replacement reactions of primary sulphonyloxy groups (for example, tosyl esters) with sodium iodide, sodium hydroxide, lithium aluminium hydride, and other reagents probably proceed by S_N2 mechanisms with carbon–oxygen fission. In the absence of participation of neighbouring groups, carbohydrate derivatives containing secondary sulphonyloxy groups attached directly to a ring are generally much less reactive than primary sulphonyloxy compounds, and sulphur–oxygen fission is usually involved in their reactions with sodium hydroxide or lithium aluminium hydride.

The relative reactivities of various tosyloxy compounds are influenced by two types of steric effect, namely, hindrance encountered by the incoming group and changes occurring in the non-bonded repulsions between substituents as the molecule passes from its initial state to the transition state. The first type is illustrated by the behaviour of the 2 : 5-di-O-tosyl-1 : 4-3 : 6-dianhydro hexitols, and the second is important in elimination and cyclization reactions which involve groups attached to a neighbouring carbon atom. The migration of three-membered oxide rings was discussed at some length.

Dr. A. B. Foster (University of Birmingham) then followed with a paper on conformational aspects of the formation and reactions of certain cyclic derivatives of carbohydrates. A number of reactions in carbohydrate chemistry are amenable to conformational analysis. Those particularly discussed were: (i) preferential formation of certain cyclic acetals in the reactions of aldehydes and polyalcohols in the presence of acid; (ii) the position of the equilibrium established in aqueous acid between a hexose and its 1 : 6-anhydro-pyranoside derivative; (iii) the remarkably facile isomerization undergone in the presence of acid by derivatives of certain 3 : 6-anhydrohexopyranosides; and (iv) a number of novel steric effects which have been encountered in the study of the reaction of borate ions with pyranoside derivatives. Some of these were explained by postulating the participation of boat forms of the carbohydrate in the reaction with borate ions. The discussions of the two papers were taken together. The speakers, particularly Dr. Schwarz, were bombarded with questions, and conformational analysis was evoked to explain various other reactions, including some biochemical changes.

The chairman for the evening session was Prof. M. Stacey. Dr. W. G. Overend (Birkbeck College, London) gave a valuable paper on the hydrolysis of glycosides. The acidic hydrolysis of O-glycosides and glycosylamines was discussed from the point of view of various factors such as the variation of the glycosidic substituent; configurational change at the glycosidic centre; variation of substituents on the glycopyranosyl residue and alteration in the size of the sugar ring. Conformational and mechanistic aspects of glycoside hydrolysis were outlined, and consideration given to the formation and hydrolysis of glycosyl phosphates and to the transglycosylation reaction.

The final comprehensive paper was given by a distinguished guest from Ottawa, Dr. R. U. Lemieux (University of Ottawa), who discussed reactions at the anomeric centre of acetylated glycopyranosyl acetates and halides. The reactions appear almost invariably to involve participation of either the ring-oxygen atom or the C(2)-substituent. The participations strongly affect the stereochemical route of reaction and appear to impose the half-chair conformation on the pyranose ring of the intermediate state. A consideration of the interactions between non-bonded atoms in the half-chair conformation of the intermediate state appears to be more fruitful in the rationalization of observed effects of configuration on reactivity than are similar considerations based on the conformation of the reactant in the ground state.

The use of proton magnetic resonance spectroscopy for establishing the conformations of sugar acetates was briefly discussed.

The symposium altogether was a lively and stimulating affair, and in the closing remarks the chairman commented on the increasing importance of applications of these newer interpretations of carbohydrate reactions in the ever-widening field of biochemistry.

ASSOCIATION OF SCHOOL NATURAL HISTORY SOCIETIES

EIGHTH ANNUAL EXHIBITION, 1956

THE eighth annual exhibition of the Association of School Natural History Societies was held at the British Museum (Natural History) on October 20. Mr. Eric Hosking, who is a founder-member of the Association, gave a lecture on "Birds in Action" before an audience of 150 children. This was illustrated by a selection of magnificent photographs of birds, for which Mr. Hosking is rightly famous. By means of electronic flash and occasionally with the use of a specially designed photo-electric camera release, some remarkable pictures had been obtained.

After the lecture, the exhibition was opened to members and to the public. A notable feature of this year's exhibition was the reduction in the number of charts and diagrams coupled with an increase in live exhibits. While it is true that the tabulation of results and their presentation in graphic form is an admirable, if not essential, way of summarizing field work, it is also true that this practice often makes a dull exhibit. Nine out of the twelve items displayed by Bishop's Stortford College were living exhibits, including an elaborate reconstruction of a portion of a refuse dump. In another exhibit were specimens of the white-lipped hedge snail (*Cepea nemoralis*), showing the many variants of shell-marking. African clawed frogs, reared at the school, made an interesting contrast to familiar British amphibians. Other examples of living freshwater animals were shown by Oundle School, Felsted School and Lord Wandsworth College, Hants. The latter school displayed also a home-made portable instrument for the field measurement of salinity in salt marshes. This operated by measuring the electrical conductivity of the water contained in a long polythene tube. The study of the natural history of mammals is a subject which has been sadly neglected by the majority of naturalists. It was therefore encouraging to see that Kimbolton School, Hunts, had begun a scheme of trapping and marking small mammals. A number of living small rodents was displayed.

Marine studies had been undertaken by Dulwich College, which displayed a large collection of marine algae and a shore transect illustrating the zonation of these species on the sea-shore. Similar work was described by Ackworth School, Yorkshire.

A pupil of Bishop's Stortford College had prepared a model to illustrate the trapping of moths at a mercury-vapour light trap. A relief model of an area of countryside, above which bird flight-lines were indicated, showed that whereas some species of bird preferred to fly along the valleys, other species tended to fly in a direction perpendicular to the contour lines. Limehurst Natural History Society (Garendon School, Loughborough, Leics.) displayed models, photographs and charts which described their island nature reserve and the wild life found there.

Lepidoptera were not so prominent in the exhibition as they were last year. Several schools showed a few in connexion with their other exhibits, but the collection shown by Tonbridge School was the most comprehensive.

Geology was represented by a soil profile across an area of poor fen, exhibited by Cranbrook School, and a selection of rock samples and fossils from an ironstone cutting brought by Uppingham School. Also included in their exhibits were owl pellets and kestrel pellets, whole and dissected. Owl pellets were featured in the displays by Oundle School, and the William Grimshaw School, London. The latter school had prepared a complete demonstration of the various stages in the dissection of a pellet, culminating in the 'reconstruction' of most of the skeleton of an individual vole from bones found in a single pellet.

It was announced that further exhibitions have been arranged in Leicester (November 24) and Leeds (May 11, 1957). Other meetings are being planned to take place in Exeter and Manchester. Further details of these meetings can be obtained from O. N. Bishop, Hon. General Secretary, A.S.N.H.S., 115 Shelly Road, Exmouth, Devon. A special edition of the Exhibition Catalogue is available (10*d*., including postage), which contains a full list of exhibits, a list of members and their addresses, and the annual reports of the committee.

In addition to those displays put on by member schools there were a number of guest exhibitors. The Amateur Entomologists' Society, the Royal Society for the Protection of Birds, the School Nature Study Union and the Universities Federation for Animal Welfare displayed their publications. The Children's Centre showed material illustrating their Saturday morning activities; a scale-model of a small portion of Epping Forest was particularly noteworthy.

O. N. BISHOP

EXPEDITION TO THE SALMON AND LEDUC GLACIERS

AN expedition to the Salmon and Leduc Glaciers was organized in 1956 by the University of Toronto under the leadership of Prof. J. A. Jacobs at the request of the Defence Research Board and the National Research Council of Canada. Eleven men took part, and the expedition lasted from the middle of May until the end of August.

The Salmon and Leduc Glaciers, which are situated near the coast of British Columbia opposite the southern tip of Alaska (approximately lat. 56° 10′ N., long. 130° 15′ W.), were chosen since they lie between the glaciers from the Juneau ice field to the north and those of the Washington Cascade and Olympic Mountains to the south, on which a considerable amount of work has already been done. The area is also interesting since the Granduc ore body lies in the mountains surrounded by these and other glaciers.

The objectives of the expedition, which forms part of Canada's glaciological programme in the International Geophysical Year, were two-fold: to train men and test equipment for use on the Canadian expedition to Northern Ellesmere Island next year, and to obtain information about British Columbia glaciers.

The whole area around the Salmon Glacier was surveyed and a map of the glacier and surrounding terrain is being prepared by Mr. K. Arnold. The main part of the programme was given over to extensive seismic and gravity surveys. The seismic programme was organized by Dr. R. R. Doell (Massachusetts Institute of Technology) and Mr. J. R. Weber (University of Alberta). In all, 354 profiles were shot, the work being greatly facilitated by the Granduc Mining Company, which provided air-borne support and the loan of a 'sno-cat' tractor. The depth of ice was generally found to be about one-half the width of the glacier, amounting to 2,000–2,400 ft.

Dr. F. S. Grant (University of Toronto) organized the gravity work. At first the survey was carried out in loops tied to a chained and levelled base-line which extended over twenty miles along the Salmon glacier and adjoining snowfields with stations every 600 ft. As the firn line receded, severe crevassing made the work difficult and a survey was carried out using two transits located on adjacent mountains, controlled by a system of visual signals. The survey was accurate to about 2 ft. in 10,000 ft.

Absolute movement of the glacier surface was determined from the movement of stakes and was of the order of 8 in. a day. Samples of ice at various depths down to 80 ft. were collected for an analysis of their tritium content. Mr. G. Falconer (University of Toronto) also carried out geomorphological studies. The rest of the party was made up of graduates and undergraduates from the Universities of British Columbia and Toronto. The results of the various projects are being prepared and will be published in detail later. A second expedition is planned for the summer of 1957, to extend the present investigations and also to undertake other glaciological studies, including micro-meteorology.

THE RADIO RESEARCH STATION

REPORT FOR 1955

THE Radio Research Organization of the Department of Scientific and Industrial Research has for many years past been the main centre of research in Britain on the propagation of radio waves; and both civilian and defence users of telecommunications look to the Radio Research Station increasingly for advice. The work is not, however, confined to the study of propagation, and during recent years attention has been given to investigations of materials used in radio components and equipment, and to the development of accurate methods of measuring power and field-strength at increasingly high frequencies. The report on this and the related work carried out during the calendar year 1955* comprises a general review made by the Radio Research Board, signed by the chairman, Sir Noel Ashbridge, together with a more detailed report on the work by Dr. R. L. Smith-Rose, director of radio research in the Department of Scientific and Industrial Research.

The report describes, with the aid of a plan, the new building which has been under construction at the Radio Research Station, Ditton Park, Slough, and has been occupied during the present year. This provides improved facilities for research and development of the laboratory type, while retaining some two hundred acres of agricultural land for field work. In addition to this central establishment, the organization maintains other observatories for measurements on the ionosphere and on atmospheric noise at Inverness, Singapore and at Port Stanley in the Falkland Islands. The latter station also works in close co-operation with a similar observatory at Port Lockroy, Graham Land, which is staffed by the Falkland Islands Dependencies Survey. Some of the work on wave propagation and also on the properties of materials is carried out, by contract arrangements or otherwise, with various research workers at University College, Ibadan, and with university groups at Cambridge, Edinburgh, London, Manchester and Swansea.

Research on wave propagation. The work conducted on radio wave propagation has been extended over a very wide range of frequencies, from about 10 kc./s. to several thousand megacycles per second. At the low-frequency end of the range, investigations are being conducted into the time and space variations of the phase and amplitude of the field received from a transmitter, since a detailed knowledge of these is essential to the development and full exploitation of long-distance radio navigational aids. At the other end of the spectrum, from a few hundred to several thousand megacycles per second, much research is in progress on the propagation of waves along the ground and through the lower atmosphere. This work is of great importance in connexion with the development of television, and also in view of the realization that the scattering of radio waves by turbulent portions of the troposphere has a practical application to communication by very short waves over distances well beyond the normal horizon. Intermediate between these extremes, the transmission of high-frequency waves (3–30 Mc./s.) by way of the ionosphere is still being actively pursued. Progress has been made in the use of the back-scatter technique in this connexion, whereby radio waves are returned from a distant point by scattering from the ground, having undergone reflexion at the ionosphere on both the outward and return journeys. During the year under review, it was found that, in the winter months, echoes were received which apparently corresponded to long hops much greater than the usual maximum of 4,000 km. for a single-hop reflexion from the ionosphere. With the view of exploring this and some associated phenomena, preparations are well advanced for the experimental comparison of this type of back-scatter with the measurement of the field-strength of signals from radio transmitters at various distances along the same great-circle path.

Research on materials. The behaviour of germanium in the form of rectangular monocrystalline filaments and in the form of commercial diodes and transistors has received a great deal of attention at the Radio Research Station. The noise characteristics of germanium are of particular interest; and observations have been made of the spectral density of noise in filaments and in point-contact and junction rectifiers biased in the reverse direction. Detailed investigations have also been made of some of the physical processes involved in the behaviour of transistors.

---

* Department of Scientific and Industrial Research. Report of the Radio Research Board with the Report of the Director of Radio Research for the Year 1955. Pp. iv+56+1 plate. (London: H.M.S.O., 1956.) 3s. 6d. net.

Some of the work which has been carried out under contract at the Imperial College of Science and Technology, London, includes research on the preparation and on properties of ferromagnetic materials. Single crystals of certain ferrites are in demand for fundamental measurements at extremely high frequencies, and a crystallization technique has been developed for the production of small single crystals. Other work at the College has included the study of artificial dielectrics which, when used in a prismatic form, can be applied to the development of an antenna system from which the direction of the radiated beam can be rapidly swung over an arc of some 15°. A greater beam swing is desirable for the purposes of radar scanning, and work is now being done on the development of materials which will make this possible.

Publications. The results of the research work described in the present report have been published in the technical press or in the journals of scientific and technical institutions; and a list of forty-one references to these publications is given in an appendix to the report. In addition, a section of the staff has surveyed all the published literature of interest to radio research workers and engineers, and nearly four thousand abstracts and references concerning work in the radio and allied fields have been published in the *Wireless Engineer* in Britain and in the *Proceedings of the Institute of Radio Engineers* in the United States.

THE QUESTION OF CORRELATION BETWEEN PHOTONS IN COHERENT LIGHT RAYS

By R. HANBURY BROWN
Jodrell Bank Experimental Station. Cheshire
AND
R. Q. TWISS
Radiophysics Laboratory, Sydney

A RECENT article by Brannen and Ferguson[1] casts doubt on our experimental demonstration[2] that the times of arrival of photons, defined as the times of ejection of photoelectrons, are correlated in two coherent beams of light. These authors quote the null result obtained by Adám, Jánossy and Varga[3] and describe in detail an experiment which they have performed themselves and which also gave a null result. They state that the existence of such a correlation would call for "a major revision of some fundamental concepts in quantum mechanics".

This last statement is in direct contradiction to our own conclusions; however, further argument should perhaps be left until our analysis, based on quantum mechanics, has been published. In the present communication we are concerned only to show that the results of Brannen and Ferguson, together with those of Adám *et al.*, are to be expected, and that they are not inconsistent with our own experiment.

The optical system described by Brannen and Ferguson was practically identical with our own, but they used a different method of detecting the correlation. A beam of light from a pinhole was divided by a half-silvered mirror into two coherent beams which illuminated independent photomultipliers. The rate of coincidence in time between the photoelectrons emitted from the two photocathodes was measured by conventional coincidence counters and compared with the random rate. It was found that the measured rate did not differ significantly from the random value, and that less than 0·01 per cent of the photons in the two beams could be in true time coincidence. On the basis of a similar experiment, Adám *et al.*[3] concluded that there was no evidence for correlation of photons and that less than 0·6 per cent could be in true coincidence.

The theoretical coincidence-rate for these two experiments does not appear to have been evaluated, and so we have derived it as follows. The average number N_0 of photoelectrons emitted by a photocathode in unit time is given by:

$$N_0 = \int_0^\infty \alpha(\nu) n_0(\nu) \mathrm{d}\nu = B\alpha(\nu_0) n_0(\nu_0) \qquad (1)$$

where $\alpha(\nu)$ is the quantum efficiency of the cathode surface at a frequency ν; $n_0(\nu)$ is the number of quanta of frequency ν incident on the cathode in unit time and unit band-width; ν_0 is the frequency of the light at which $\alpha(\nu)n_0(\nu)$ has its maximum value; B is the equivalent band-width of the light in cycles per second. If τ is the resolving time of the equipment and $2\tau N_0 \ll 1$, a condition which must apply to this technique, then the average number of random coincidences $\overline{C}_R$ to be expected in a time T_0 is given by:

$$\overline{C}_R = 2\tau N_0^2 T_0 \qquad (2)$$

When the light beams are correlated we have shown (unpublished work) that, under practical conditions, there will be an additional average number of coincidences C_S, where

$$C_S = \frac{T_0}{2}\int_0^\infty \alpha^2(\nu) n_0^2(\nu) \mathrm{d}\nu \,.\, \Phi(\theta D/\lambda_0) \qquad (3)$$

and where θ is the apparent angular diameter of the source viewed from the photocathodes; the photocathodes are squares of size $D \times D$; λ_0 is the mean wave-length of the light; it is assumed that the light is unpolarized and that $B \gg 1/\tau$. The quantity $\Phi(\theta D/\lambda_0)$ is a function which represents the degree of coherence of the light over the area of the photocathodes and is equal to unity when $(\theta D/\lambda_0) \ll 1$.

It is convenient to introduce a parameter σ, the spectral density of the light, defined by:

$$\alpha(\nu_0) n_0(\nu_0) \sigma = \int_0^\infty \alpha^2(\nu) n_0^2(\nu) \mathrm{d}\nu \Big/ \int_0^\infty \alpha(\nu) n_0(\nu) \mathrm{d}\nu \qquad (4)$$

where σ usually lies in the range of $0{\cdot}5 < \sigma < 1$. We may now write the expected number of true time coincidences, which is independent of τ, as

$$C_S = \frac{N_0{}^2 T_0 \sigma}{2B} \cdot \Phi(\theta D/\lambda_0) \qquad (5)$$

It should also be noted that the ratio of the number of true coincidences to the random rate is given by:

$$C_S/\overline{C}_R = \frac{1}{4\tau B} \cdot \sigma \cdot \Phi(\theta D/\lambda_0) \qquad (6)$$

and is independent of the total number of incident quanta. The fractional number of *photoelectrons* in true coincidence δ_c is given by:

$$\delta_c = \frac{N_0 \sigma}{2B} \cdot \Phi(\theta D/\lambda_0) \qquad (7)$$

and is linearly proportional to the number of incident quanta per unit band-width.

The root mean square fluctuation c_R in the number of random coincidences is defined as:

$$c_R{}^2 = \overline{C_R{}^2} - (\overline{C}_R)^2 \qquad (8)$$

and, neglecting fluctuations introduced by the photomultiplier itself, it is given by

$$c_R = N_0 (2\pi T_0)^{1/2} \qquad (9)$$

Thus the ratio of the true coincidences to the root mean square fluctuations in the coincidence-rate, which we shall refer to as the signal-to-noise ratio, is given by:

$$C_S/c_R = \alpha(\nu_0) n_0(\nu_0) \sigma \frac{1}{\sqrt{2}} \cdot \Phi \frac{\theta D}{\lambda_0} \left(\frac{T_0}{4\tau}\right)^{1/2} \qquad (10)$$

or alternatively,

$$C_S/c_R = \frac{\int_0^\infty \alpha^2(\nu) n_0{}^2(\nu) d\nu}{\int_0^\infty \alpha(\nu) n_0(\nu) d\nu} \cdot \frac{1}{\sqrt{2}} \cdot \Phi \frac{\theta D}{\lambda_0} \left(\frac{T_0}{4\tau}\right)^{1/2} \qquad (11)$$

Equation (11) can be compared directly with equations (1) and (2) of our previous paper[2], which refers to the alternative technique of correlating the fluctuations in the anode currents of the two photomultipliers by means of a linear multiplier. It can be shown that the effective resolving time of a linear system with a band-width b is given by $\tau \simeq 1/\pi b$, and, if this substitution is made in our original equations, a comparison shows that the two techniques give approximately the same signal-to-noise ratios. In making this comparison, it must be remembered that the equations given for the counting technique are only valid for the condition $2\tau N_0 \ll 1$.

We shall now substitute the parameters of the two coincidence-counter equipments into the equations given above. The values which have been taken for these experiments are shown in Table 1. The band-width of the light is not stated by Brannen and Ferguson, and so we have assumed that their high-pressure mercury-arc lamp, when viewed through an interference filter, gave a line-width of at least 10 A. at 4358 A. The value of $\Phi(\theta D/\lambda_0)$ depends in detail on the geometry of the equipment, and its calculation is too long to give here. In the case of Adám *et al.*, we have taken the same values for B and $\Phi(\theta D/\lambda_0)$ as those assumed for Brannen and Ferguson; this is probably an optimistic estimate, and in practice their equipment was probably even less sensitive.

Table 1. A COMPARISON OF THE THEORETICAL PERFORMANCE OF THREE EQUIPMENTS USED TO TEST THE CORRELATION BETWEEN PHOTONS IN TWO COHERENT BEAMS OF LIGHT

		Brannen and Ferguson (ref. 1)	Adám, Jánossy and Varga (ref. 3)	Hanbury Brown and Twiss (ref. 2)
Total number of photoelectrons incident per sec. on each cathode	N_0	5×10^4 ($\alpha = 0{\cdot}1$)	100 ($\alpha = 0{\cdot}003$)	3×10^9 ($\alpha = 0{\cdot}15$)
Resolving time of the equipment (sec.)	τ	5×10^{-9}	2×10^{-6}	10^{-8}*
A factor which expresses the degree of coherence of the light over each cathode	$\Phi \frac{\theta D}{\lambda_0}$	0·1	0·1 ?	0·5
Effective band-width of the light (c./s.)	B	$\geqslant 1{\cdot}5 \times 10^{12}$ ($\sigma = 1$)	$\geqslant 1{\cdot}5 \times 10^{12}$ ($\sigma = 1$)	10^{13} ($\sigma = 0{\cdot}5$)
Fractional number of photons to be expected in true time-coincidence	ρ_c	$\leqslant 1{\cdot}7 \times 10^{-8}$	$\leqslant 10^{-9}$	$2{\cdot}5 \times 10^{-4}$*
Time of observation to obtain a significant correlation (3 times r.m.s. fluctuation)	T	$\geqslant$ 1,000 years	$\geqslant 10^{11}$ years	5 min.

* A coincidence counter was not used in this experiment. The correlation was measured in a linear multiplier, using a band-width of about 30 Mc./s.

The fraction $\rho_c \simeq \delta_c/\alpha(\nu_0)$ of *photons* to be expected in true time-coincidence was found from equation (7). Brannen and Ferguson found that less than 10^{-4} were in coincidence, while Adám *et al.* found less than $0{\cdot}6 \times 10^{-2}$. It can be seen from Table 1 that the corresponding expected values are $1{\cdot}7 \times 10^{-8}$ and 10^{-9}.

We have also calculated, from equation (10), the time T_0 for which counts would have to be observed to obtain a significant correlation; a significant result has been defined as an excess of coincidences amounting to at least three times the root mean square fluctuation in the random coincidence-rate. The time for which Brannen and Ferguson would have to count is 1,000 years, while Adám, Jánossy and Varga would have to count for 10^{11} years.

In our own experiment a significant result was obtained in about 10 min. This confirms the value of 5 min., shown in Table 1, which was calculated from the equations given in our previous paper[2]. A further confirmation that our analysis is quantitatively correct is given by our recent measurements[4] on the star Sirius *A*.

We conclude that the results obtained by Brannen and Ferguson, and by Adám *et al.*, are to be expected theoretically and are not in conflict with our own. Their equipment was too insensitive to detect a significant correlation by at least four orders of magnitude. In the case of Adám *et al.*, the equipment was too insensitive by at least seven orders of magnitude.

[3] Adám, A., Jánossy, L., and Varga, P., *Acta Physica Hungarica*, **4**, 301 (1955).
[4] Hanbury Brown, R., and Twiss, R. Q., *Nature*, **178**, 1046 (1956).

Brannen and Ferguson[1] have reported experimental results which they believe to be incompatible with the observation by Hanbury Brown and Twiss[2] of correlation in the fluctuations of two photoelectric currents evoked by coherent beams of light. Brannen and Ferguson suggest that the existence of such a correlation would call for a revision of quantum theory. It is the purpose of this communication to show that the results of the two investigations are not in conflict, the upper limit set by Brannen and Ferguson being in fact vastly greater than the effect to be expected under the conditions of their experiment. Moreover, the Brown–Twiss effect, far from requiring a revision of quantum mechanics, is an instructive illustration of its elementary principles. There is nothing in the argument below that is not implicit in the discussion of Brown and Twiss, but perhaps I may clarify matters by taking a different approach.

Consider first an experiment which is simpler in concept than either of those that have been performed, but which contains the essence of the problem. Let *one* beam of light fall on *one* photomultiplier, and examine the statistical fluctuations in the counting-rate. Let the source be nearly monochromatic and arrange the optics so that, as in the experiments already mentioned, the difference in the length of the two light-paths from a point A in the photocathode to two points B and C in the source remains constant, to within a small fraction of a wave-length, as A is moved over the photocathode surface. (This difference need not be small, nor need the path-lengths themselves remain constant.) Now it will be found, even with the steadiest source possible, that the fluctuations in the counting-rate are slightly greater than one would expect in a random sequence of independent events occurring at the same average rate. There is a tendency for the counts to 'clump'. From the quantum point of view this is not surprising. It is typical of fluctuations in a system of bosons. I shall show presently that this extra fluctuation in the single-channel rate necessarily implies the cross-correlation found by Brown and Twiss. But first I propose to examine its origin and calculate its magnitude.

Let P denote the square of the electric field in the light at the cathode surface in one polarization, averaged over a few cycles. P is substantially constant over the photocathode at any instant, but as time goes on it fluctuates in a manner determined by the spectrum of the disturbance, that is, by the 'line shape'. Supposing that the light contains frequencies around ν_0, we describe the line shape by the normalized spectral density $g(\nu-\nu_0)$. The width of the distribution g, whether it be set by circumstances in the source itself or by a filter, determines the rate at which P fluctuates. For our purpose, the stochastic behaviour of P can be described by the correlation function $\overline{P(t)\,P(t+\tau)}$, which is related in turn to $g(\nu-\nu_0)$ by[3]

$$\overline{P(t)P(t+\tau)} = \overline{P}^2(1+|\rho|^2),$$

$$\text{where } \rho = \int_{-\infty}^{\infty} g(x) \exp 2\pi i\tau x \, dx \qquad (1)$$

For the probability that a photoelectron will be ejected in time dt, we must write $\alpha P dt$, where α is constant throughout the experiment. It makes no difference whether we think of P as the square of an electric field-strength or as a photon probability density. (In this connexion the experiment of Forrester, Gudmundsen and Johnson[4] on the photoelectric mixing of incoherent light is interesting.) Assuming one polarization only, and one count for every photoelectron, we look at the number of counts n_T in a fixed interval T, and at the fluctuations in n_T over a sequence of such intervals. From the above relations, the following is readily derived:

$$\overline{n^2_T} - \overline{n}^2_T = \overline{n}_T(1+\alpha\overline{P}\tau_0) \qquad (2)$$

$$\text{where } \tau_0 = \int_{-\infty}^{\infty} |\rho|^2 d\tau$$

and it has been assumed in deriving (2) that $T \gg \tau_0$. Now $\alpha\overline{P}$ is just the average counting-rate and τ_0, a correlation time determined by the light spectrum, is approximately the reciprocal of the spectral bandwidth $\Delta\nu$; in particular, if $\Delta\nu$ is the full width at half intensity of a Lorentzian density function, $\tau_0 = (\pi\Delta\nu)^{-1}$, while if $\Delta\nu$ is the width of a rectangular density function, $\tau_0 = \Delta\nu^{-1}$. We see that the fractional increase in mean-square fluctuation over the 'normal' amount is independent of T, and is about equal to the number of counts expected in an interval $1/\Delta\nu$. This number will ordinarily be very much smaller than one. The result, expressed in this way, does not depend on the counting efficiency.

If one insists on representing photons by wave packets and demands an explanation in those terms of the extra fluctuation, such an explanation can be given. But I shall have to use language which ought, as a rule, to be used warily. Think, then, of a stream of wave packets, each about $c/\Delta\nu$ long, in a random sequence. There is a certain probability that two such trains accidentally overlap. When this occurs they interfere and one may find (to speak rather loosely) four photons, or none, or something in between as a result. It is proper to speak of interference in this situation because the conditions of the experiment are just such as will ensure that these photons are in the same quantum state. To such interference one may ascribe the 'abnormal' density fluctuations in any assemblage of bosons.

Were we to carry out a similar experiment with a beam of electrons, we should, of course, find a slight suppression of the normal fluctuations instead of a slight enhancement; the accidentally overlapping wave trains are precisely the configurations excluded by the Pauli principle. Nor would we be entitled in that case to treat the wave function as a classical field.

Turning now to the split-beam experiment, let n_1 be the number of counts of one photomultiplier in an interval T, and let n_2 be the number of counts in the other in the same interval. As regards the fluctuations in n_1 alone, from interval to interval, we face the situation already analysed, except that we shall now assume both polarizations present. The fluctuations in orthogonal polarizations are independent, and we have, instead of (2),

$$\overline{\Delta n_1^2} = \overline{n_1^2} - \overline{n}_1^2 = \overline{n}_1(1+\tfrac{1}{2}\overline{n}_1\tau_0/T) \qquad (3)$$

where n_1/T has been written for the average counting-rate in channel 1. A similar relation holds for n_2. Now if we should connect the two photomultiplier outputs together, we would clearly revert to a single-channel experiment with a count $n = n_1 + n_2$. We must then find:

$$\overline{\Delta n^2} = \bar{n}\,(1 + \tfrac{1}{2}\bar{n}\tau_0/T) \qquad (4)$$

But $\overline{\Delta n^2} = \overline{(\Delta n_1 + \Delta n_2)^2}$

$$= \bar{n}_1(1+\tfrac{1}{2}\bar{n}_1\tau_0/T) + \bar{n}_2(1+\tfrac{1}{2}\bar{n}_2\tau_0/T) + \overline{2\Delta n_1\Delta n_2} \qquad (5)$$

From (4) and (5) it follows that:

$$\overline{\Delta n_1\Delta n_2} = \tfrac{1}{2}\bar{n}_1{}^2\tau_0/T \qquad (6)$$

This is the positive cross-correlation effect of Brown and Twiss, although they express it in a slightly different way. It is merely another consequence of the 'clumping' of the photons. Note that if we had separated the branches by a polarizing filter, rather than a half-silvered mirror, the factor 1/2 would be lacking in (4), and (5) would have led to $\overline{\Delta n_1\Delta n_2} = 0$, which is as it should be.

If we were to split a beam of electrons by a non-polarizing mirror, allowing the beams to fall on separate electron multipliers, the outputs of the latter would show a negative cross-correlation. A split beam of classical particles would, of course, show zero cross-correlation. As usual in fluctuation phenomena, the behaviour of fermions and the behaviour of bosons deviate in opposite directions from that of classical particles. The Brown–Twiss effect is thus, from a *particle* point of view, a characteristic quantum effect.

It remains to show why Brannen and Ferguson did not find the effect. They looked for an increase in coincidence-rate over the 'normal' accidental rate, the latter being established by inserting a delay in one channel. Their single-channel rate was 5×10^4 counts per sec., their accidental coincidence rate about 20 per sec., and their resolving time about 10^{-8} sec. To analyse their experiment one may conveniently take the duration T of an interval of observation to be equal to the resolving time. One then finds that the coincidence-rate should be enhanced, in consequence of the cross-correlation, by the factor $(1 + \tau_0/2T)$. Unfortunately, Brannen and Ferguson do not specify their optical band-width; but it seems unlikely, judging from their description of their source, that it was much less than 10^{11} cycles/sec., which corresponds to a spread in wavelength of rather less than 1 A. at 4358 A. Adopting this figure for illustration, we have $\tau_0 = 10^{-11}$ sec., so that the expected fractional change in coincidence-rate is 0·0005. This is much less than the statistical uncertainty in the coincidence-rate in the Brannen and Ferguson experiment, which was about 0·01. Brown and Twiss did not count individual photoelectrons and coincidences, and were able to work with a primary photoelectric current some 10^4 times greater than that of Brannen and Ferguson. It ought to be possible to detect the correlation effect by the method of Brannen and Ferguson. Setting counting efficiency aside, the observing time required is proportional to the resolving time and inversely proportional to the square of the light flux per unit optical band-width. Without a substantial increase in the latter quantity, counting periods of the order of years would be needed to demonstrate the effect with the apparatus of Brannen and Ferguson. This only adds lustre to the notable achievement of Brown and Twiss.

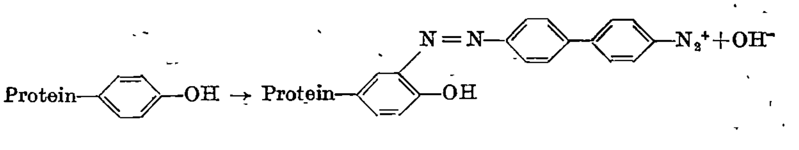
A CYTOCHEMICAL REACTION FOR NUCLEOPROTEIN

By E. A. BARNARD and Prof. J. F. DANIELLI

Zoology Department, King's College, London, W.C.2

WE have recently completed a study of a cytochemical reaction for protein which appears to be specific for protein in a special form of combination with nucleic acid.

When a diazonium hydroxide is applied to a tissue section, the following components may react: (1) tyrosine and histidine and perhaps tryptophan side-chains in proteins, for example:



(2) some aliphatic —NH_2 and —NH— groups to give triazenes; (3) phenols, certain bases and similar compounds of low molecular weight; (4) some doubt has existed in the past as to whether the nucleic acid bases might couple. They do not appear to do so *in vitro*; but the possibility exists that they might do so in the peculiar physico-chemical conditions prevailing in a tissue section.

If, before the diazonium hydroxide is applied, the section is treated with benzoyl chloride, all components capable of reacting with diazonium hydroxides should react with the benzoyl chloride, so that subsequent reaction with diazonium hydroxide should be blocked. Consequently, pretreatment of sections with benzoyl chloride should entirely eliminate the formation of chromophores. In fact, it does not: after benzoylation there is a residual (mainly nuclear) reaction[1].

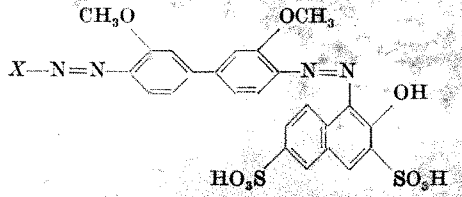
The nature of this tissue reactant which is able to react with diazonium hydroxide after benzoylation has been the object of our present study. This reaction sequence was first tried by Mitchell[2], who found that some reaction persisted, which he attributed to nucleic acid. The results of his reaction, using benzoyl chloride in aqueous sodium hydroxide, were not very satisfactory, but indicated that some interesting effects might exist.

To develop this procedure into a satisfactory cytochemical process the following steps were necessary: (1) to find conditions under which benzoylation and coupling with diazonium hydroxide give reproducible coloration of the section; (2) to determine, by fractionation, which major tissue components displayed the reaction; (3) to identify, by analysis, the nature of the groupings which were responsible for the coloration of the reactant; (4) to determine the cellular distribution of the reactant; (5) to determine the significance of the reaction.

1. *Cytochemical routine.* The method is normally applied to frozen-dried tissue, embedded in wax and sectioned. After removal of wax, the sections are fixed in absolute alcohol, washed in acetonitrile, and benzoylated for about three hours at room temperature in dry acetonitrile containing 10 per cent (w/v) benzoyl chloride and one equivalent of pyridine. Benzoylation in this medium always goes uniformly and reproducibly, provided all the materials are dry. The sections are washed in alcohol, taken down to water and coupled with a solution of tetrazotized dianisidine in sodium veronal buffer (*p*H 9) at about 4° C. for 12 min. They are washed thoroughly with buffer, 0·05 *N* hydrochloric acid and water, and then to enhance the colour are coupled further with a solution of a naphthol, for example, β-naphthol (0·1 per cent in 0·5 per cent sodium carbonate) for 12 min., all operations being carried out in the ice-bath. After washing in sodium carbonate solution and in water, the sections are taken up to absolute alcohol and mounted in balsam.

2. *Fractionation studies.* To identify the tissue component responsible, tissue was treated in bulk using conditions comparable to those encountered in the sections. 2-Naphthol-3,6-disulphonic acid was used as the naphthol for conferring water-solubility and on account of its chemical stability. Isolated chicken erythrocyte nuclei were found to possess several advantages as a test material. Smears of the final product showed discrete nuclei similar in appearance to those in a treated chicken blood smear. Fractionation of this material involved solvent extraction of lipid followed by the removal of nucleic acid by hot trichloracetic acid or by boiling *N* hydrochloric acid. Neither the lipid nor the nucleic acid extracts contained any of the dye component, although the acid extracts appeared to contain all the purines and pyrimidines present. Brief extraction of the residue with alkali gave a highly coloured solution, leaving a final residue containing very little dye. Selective precipitation of the extract, using the polyelectrolyte properties of the dye-containing component, separated the latter from some non-coloured proteins present. The dye-containing compound was readily soluble in slightly alkaline solution. It appeared to be macromolecular, and on reduction of the dye and hydrolysis a typical amino-acid mixture was obtained. The dye residue thus appeared to be linked chemically to a protein component of the nucleus, or at least to be very strongly associated with such a component. We have not been able to find lipoid, nucleic acid or polysaccharides which have reacted to give a coloured product. Thus it remained to determine which protein components were responsible for the reaction.

3. *Identification of the active group* (*X* in the structure):



Hydrolysis of the coloured protein fraction to yield the dye-containing molecule was sought. Proteolytic enzymes proved ineffective, presumably owing to the benzoyl[3] and dye groups present. Acid hydrolysis under the usual conditions destroyed the dye residue, as did alkaline hydrolysis, although more slowly (compare observations of Rowe and Dangerfield[4]). The only medium found to give satisfactory hydrolysis of the peptide bonds with conservation of the azo links was a solution of cetyl trimethyl ammonium bromide (0·015 *M*) in 0·3 *N* sodium hydroxide solution, under reflux. This method was suggested by the work of Steinhardt and Fugitt[5], who used anionic detergents in dilute acid for catalytic hydrolysis. Here we may be observing a combination of catalytic and protective effects, the latter probably due to binding of the cationic pole by the sulphonic groups of the dye residue. Ion-exchange resin chromatography of the hydrolysate removed the detergent and separated the dye component from the normal amino-acids. Paper chromatography of the dye fraction in two solvents gave one main spot and a weaker one which appeared to arise from a small amount of destruction of the major component. The main spot was unchanged on further hydrolysis. Identification of this bis-azo compound by paper chromatography was difficult owing to the size and nature of the residue attached to *X*, the group derived from the tissue. The two azo links were therefore reduced with sodium hydrosulphite to give amino derivatives (after purification of the dye solution by alumina column chromatography). Paper chromatography of the reduction products separated dianisidine, an amino derivative of 2-naphthol-3,6-disulphonic acid, and an unknown ninhydrin-positive compound, having R_F 0·18 in butanol/acetic acid/water (4 : 1 : 5). Extraction of the latter compound from the paper and examination of its ultra-violet spectrum (in distilled water) showed strong absorption only below 2350 A., a spectrum incompatible with a derivative of tyrosine or tryptophan. Synthesis and separation on paper of 4-amino-tyrosine and 2- and 4-amino-histidines and comparison of their R_F values in different solvents and of their ultra-violet spectra gave results confirming the exclusion of tyrosine and consistent with a derivation from histidine.

Prof. W. C. Price and his group at the Wheatstone Physics Laboratory, King's College, kindly agreed to examine eluates from paper chromatograms by infra-red spectroscopy. Eluate solutions were evaporated to deposit samples on silver chloride disks. Identification was complicated by two factors: (1) the tendency of histidines (but not of tyrosine) to combine with a fraction from the paper, and (2) the tendency of amino-histidine to polymerize. Details of these complications will be dealt with in another communication. However, the behaviour of the compound suspected of being amino-histidine was identical with that of synthetic amino-histidine. Hence all the evidence examined appears to lead to the conclusion that the coupling reaction in the nucleus after benzoylation is given by histidine residues in a protein fraction.

4. *Distribution of the reactant.* Sections of a considerable number of animal tissues having structures and activities of various types have now been subjected to this blocked tetrazonium reaction. The tissues include rat liver, kidney, intestine, pancreas, stomach, lung, trachea, skeletal and cardiac muscle, spleen, skin, cerebellum, bone marrow, ovary, testis, adrenal, pituitary, thyroid and Walker rat sarcoma; mouse ascites cells; avian erythrocytes and other avian tissues. The nuclei are always consistently positive, showing an intranuclear distribution of stain which appears to be very similar to that after a Feulgen reaction on similar sections. Rat pancreas sections in which the blocked tetrazonium stain was photographed and then removed by titanous chloride reduction, and which were subsequently reacted by the Feulgen method and re-photographed, showed a superimposable localization of the two stains in the same nucleus. Although the cytoplasm is negative after benzoylation in many cases, there are certain sites in which it remains positive, although less intensely so than with coupling alone. These include the cytoplasm of exocrine cells in the pancreas, which contrast with neighbouring endocrine and connective tissue cells. Goblet cells in the intestinal mucosa (Fig. 2) are strongly positive, although extracellular mucus appears to be negative. Certain other extranuclear structures in specific sites also appear to react to some extent, but an accurate evaluation is awaiting quantitative measurements.

5. *Significance of the reaction.* It remains to inquire why the histidine residues implicated are not benzoylated, as they are *in vitro*, and in the cytoplasm in most cases. A clue to this problem may lie in our discovery that brief exposure to water, for times of the order of one minute, prior to benzoylation abolishes the later coupling reaction. The positive reaction is shown by frozen-dried sections fixed and benzoylated in anhydrous media; if this condition is not observed, unsatisfactory results may be obtained. Deliberate taking down to water and renewed hydration after embedding in wax and before benzoylation give a uniformly negative result, which is not due to the removal of any substance at that stage. We have interpreted the reaction in terms of 'protective bonds', which after dehydration exist between certain imidazole groups and other groups presumed to be normally in some particular relation to them. These bonds protect imidazole rings from reaction with benzoyl chloride in anhydrous medium. In more polar conditions this bond is labile, hence coupling can occur in aqueous solution. Benzoylation only occurs at this site if the imidazole group is first exposed by water treatment. Since the effect is not re-established by a second dehydration, we presume the elements involved were initially related to each other in a specific way.

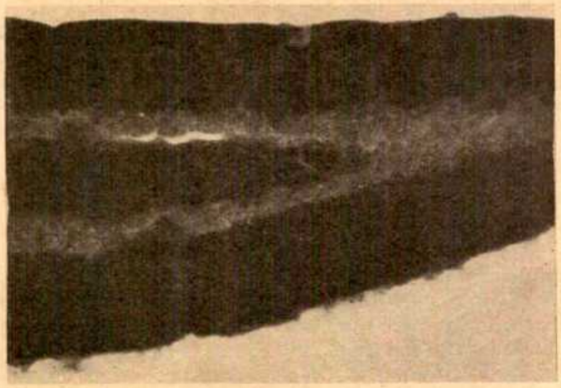


Fig. 1. Rat intestine, tetrazonium coupled

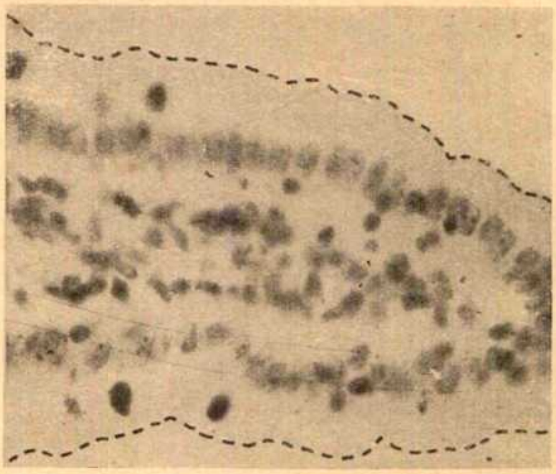

Fig. 2. Rat intestine, benzoylated and tetrazonium coupled

The close association shown above between this nuclear component and deoxyribonucleic acid suggests that a protein naturally associated with the acid is involved. Histidine residues could form bonds with nucleic acid in at least four ways: (1) with phosphate groups in the manner usually suggested for arginine and lysine (it is interesting to note that phosphate groups on imidazole may in some cases be readily transferred[6]); (2) by hydrogen bonding on to suitable partners; (3) by chelation through a metal, using the specific complexing properties of the imidazole ring (evidence has been claimed for metal bridges in nucleoproteins[7]); (4) by combination with the pentose due to the ability of histidine to form strong bonds (perhaps as a special case of (2)) with carbohydrate in certain circumstances[8]. It is not possible to predict at present which of these bonds would have the properties found here, but the particular environment concerned could well confer such properties even if model systems did not show them (cf. evidence adduced by Fraenkel-Conrat[9] for stabilization by protein structures of otherwise unstable bonds including some involving imidazole). Some simple chemical properties of the imidazole ring of histidine are known to be greatly affected by changes at the α-carbon such as incorporation into a peptide chain[10].

The cytoplasmic reactions mentioned, although not yet analysed biochemically, appear to be associated usually with synthetic activity and high content of ribonucleic acid (for example, pancreas) or with muco-protein secretion (goblet cells). Both these may well involve bonds of the type discussed, and can thus be fitted into the same scheme. We appear to be observing cytochemically an indication not of the stoichiometric amount of a particular substance or group present (an aim probably not often achieved) but the extent to which a particular type of bonding is present. The facts that the reaction appears normally to be limited to nucleoprotein, that the shielding of the histidine from benzoylation is readily destroyed after fixation, and that the relationship between protein and nucleic acid is specific, and cannot be readily reproduced by mixing proteins and nucleic acids, lead us to believe that the reaction detects an interaction between nucleic acid and protein which may well be of major importance in the biological activity of the cell. It may be that information is derivable by these methods on such important consequences of nucleic acid–protein relationships as the genic structure of the cell and protein synthesis. To this end further investigation into the precise nature of the interactions concerned is being pursued.

In conclusion, we should like to direct attention to the fact that the complex physico-chemical conditions prevailing in tissues make it impossible to predict with certainty which tissue components will react with any chemical reagent. Thus in the evaluation of all chromogenic techniques it is necessary to identify, by analysis, the tissue components which actually do react with the reagents used. In dealing with the very small amounts of material of this type that can reasonably be prepared, it may be found useful in other cases to combine ion-exchange and paper chromatography with ultra-violet and infra-red spectroscopy, and to find methods of protecting sensitive residues during the often drastic degradation procedures necessary.

We thank Dr. L. G. Bell for valuable help. We are indebted to Prof. W. C. Price, Mr. R. Bradbury, Dr. M. A. Ford and Dr. G. R. Wilkinson for carrying out the infra-red measurements. One of us (E. A. B.) acknowledges financial assistance from the British Empire Cancer Campaign and from the Nuffield Foundation.

MORPHOLOGY OF RESTING VACCINIA VIRUS

By Dr. D. PETERS

Virus Department, Institute of Tropical Diseases, Hamburg

IN previous electron microscopic studies it was shown that pepsin treatment of vaccinia elementary bodies discloses a nucleus-like inner body[1], which contains deoxyribonucleic acid[2,3]. If digestion is performed after Chabaud-fixation, this body has an annular shape caused by a central depression. With regard to its ring-like arrangement, it was concluded that the material containing deoxyribonucleic acid could not be identified with the area of higher density in the centre of untreated particles[4,5]. This conclusion could further be supported by studies on the influence of other fixatives combined with pepsin or papain, respectively, on ultra-thin sections and on material prepared by the critical point method. Suspensions of virus particles collected from rabbit skin and purified by differential centrifugation were used.

In this stage of development the elementary bodies of vaccinia virus are brick shaped. Material prepared by the critical point method[6] usually revealed virus particles attached to the film in a vertical position. These demonstrated more contrast (Fig. 1) than those attached in the usual horizontal manner. The outline of vertically orientated particles revealed a central thickening. A stereoscopic study of inclined particles proved the identity of the thickening and the central elevation previously seen in shadowed elementary bodies[5]. Occasionally vertically orientated particles are also found in material prepared in the conventional manner[1]. It is important, therefore, to keep in mind that variations of internal structures of enzyme-treated particles may represent elementary bodies of different positions. The ratio of vertically orientated particles increased when drying during the different steps of treatment was avoided.

Enzymatic digestion was performed under varying conditions of enzyme concentration, digestion time, salt solution and particularly pH value. The pepsin-resistant annular structure was best preserved by fixation with ethanol–acetic acid (15 : 1) (Fig. 2*a*). It could also be demonstrated after treatment with buffered formaldehyde (pH 7·2) and occasionally in the unfixed state. In some virus particles which happened to be prepared vertically, this structure exhibited its lateral aspect, thus showing a bar- or bean-shaped outline. Buffered osmic acid (pH 7·2), the commonly recommended fixative for electron-optical purposes, rendered the elementary bodies resistant to pepsin treatment. This obstacle could be overcome by performing the pepsin treatment in a reducing medium like cysteine or thioglycolic acid. In spite of a more condensed shape of the inner body, the central depression was usually preserved (Fig. 2*b*). In view of the following results, it is assumed that some shrinkage of the inner body generally occurred, due to the influence of acid medium and pepsin-

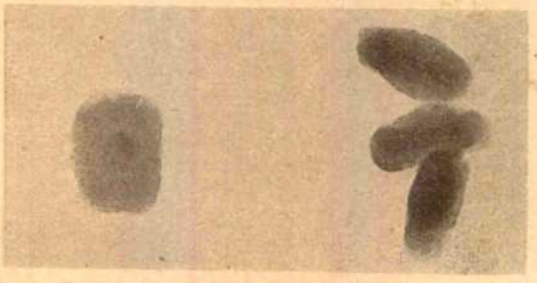

Fig. 1. Vaccinia elementary bodies fixed by osmic acid prepared by the critical point method (× 50,000)

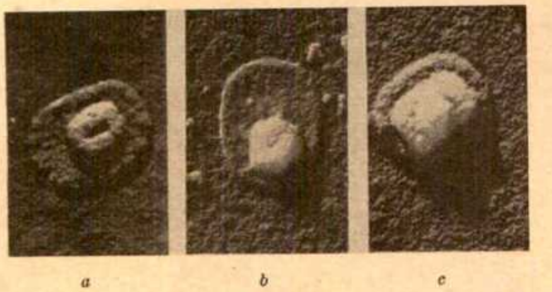

Fig. 2. Elementary bodies after pepsin treatment, uranium shadowed (× 50,000). *a*, ethanol-acetic acid fixation (15 min.), cryst. pepsin (0·02 per cent, *p*H 1·5, 37°, 2 hr.); *b*, osmic acid fixation (*p*H 7·2, 15 min.), cryst. pepsin (0·02 per cent, *p*H 2·0, 37°, 2 hr.) in presence of cysteine (0·1 mol.); *c*, ethanol-acetic acid fixation (15 min.), cryst. pepsin (0·02 per cent, *p*H 3·5, 37°, 2 hr.) activated by cysteine (0·1 mol.). Note the shadow outline

induced structural destabilization. This effect was more pronounced after osmic acid treatment. This may be explained by the fact that osmic acid does not cause precipitation as the aforementioned organic fixatives do.

In studies on unfixed or ethanol–acetic acid fixed particles it was found that addition of cysteine extended the *p*H range of peptic digestion up to *p*H 4·5. From *p*H 2·5 onwards—to a maximum at *p*H 3·5—increasing numbers of elementary bodies were observed showing an additional distinct structure at the site of the central depression (Fig. 2*c*). In previous studies this body could only be demonstrated irregularly after incomplete enzymatic treatment[5]. Due to its position at the centre of the annular body, this structure represents a constituent of the central opaque area of untreated particles. The comparison of Figs. 2*a*, 2*b* and 2*c* demonstrates that shrinkage of the annular inner body decreases with increasing *p*H.

In contrast to pepsin, papain offered the advantage of a more neutral reaction. Activated crystallized papain (Worthington) did not attack the structure of untreated elementary bodies. After previous denaturation (fixation with ethanol–acetic acid or buffered osmic acid), however, a reaction took place at *p*H values above 3·2. Papain exhibited optimum efficiency in a citric acid medium. Up to *p*H 4·8 an annular inner body was demonstrated (Fig. 3*a*) similar to that known from pepsin treatment. It was rod- or bean-shaped when exposed from its lateral aspect. With the increased *p*H value a lesser degree of inner body shrinkage was observed. The ring-like structure proved to be resistant to pepsin, and conversely the pepsin-induced inner body resisted papain treatment at *p*H 4·2. This is taken as a proof of their identity. Parallel to previous work with pepsin[2,3], the presence of deoxyribonucleic acid in this structure could be demonstrated by the combined action of deoxyribonuclease (*p*H 6·0) and papain (*p*H 4·2), which accordingly led to almost empty membranes.

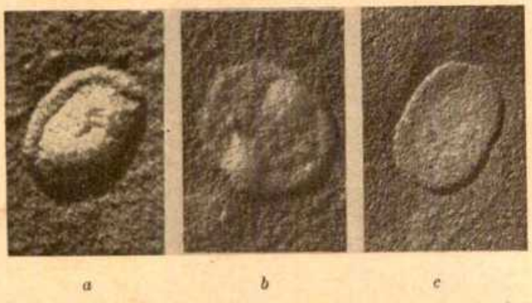

Fig. 3. Elementary bodies after papain treatment, uranium shadowed (× 50,000). *a*, ethanol–acetic acid fixation (15 min.), cryst. papain (0·2 per cent, *p*H 4·2, 37°, 2 hr.) activated by thioglycolic acid (0·1 mol.) in citrate (0·1 mol.); *b*, osmic acid fixation (*p*H 7·2, 15 min.), cryst. papain (0·02 per cent, *p*H 7·0, 37°, 20 hr.) activated by thioglycolic acid (0·1 mol.) in pure water; *c*, osmic acid fixation (*p*H 7·2, 15 min.), cryst. papain (0·2 per cent, *p*H 6·0, 37°, 20 hr.) activated by cysteine (0·1 mol.) in citrate (0·1 mol.)

Among papain-treated virus particles, some were always found showing the distinct structure at the site of the central depression. Their number increased with decreasing *p*H values. At *p*H 3·4, in addition to some intact particles, only such elementary bodies were demonstrated. The picture was the same as that seen after digestion with activated pepsin at *p*H 3·5 (Fig. 2*c*). Obviously, so far, there is good agreement between the results gained by pepsin and by papain treatment.

From *p*H 5·0 to about *p*H 9 the material containing deoxyribonucleic acid was not protected against papain digestion. Almost empty membranes resulted (Fig. 3*c*). A few of those, however, contained some material at the centre or two distinct small bodies, respectively, arranged at opposite sites of the membrane along its shorter axis. These structures were regularly demonstrated when particles fixed with osmic acid were treated with papain at a low concentration and *p*H 7·0 (Fig. 3*b*). They appear to be identical with the aforementioned distinct structure which is assumed to participate in the central opaque zone of untreated particles. Horizontally orientated elementary bodies exhibited this material within the centre. In the vertical position, however, it appeared to be separated into two bodies at the rim of the membrane.

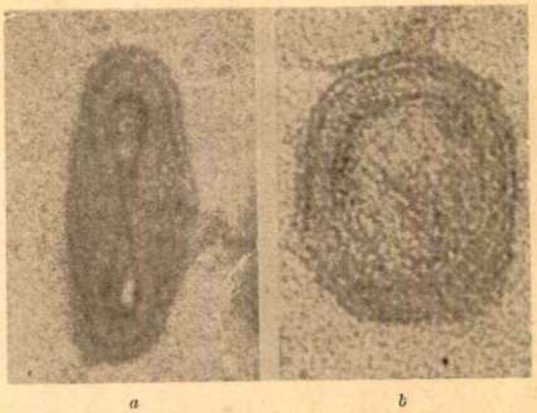

Fig. 4. Sectioned elementary bodies, fixed in osmic acid (*p*H 7·2, 4 hr.), methacrylate-imbedded, prepared on carbon film (× 130,000). *a*, vertical section; *b*, horizontal section. Note the double outline around the core

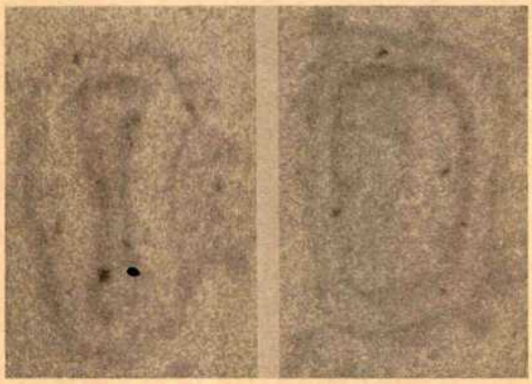
These results agree with the aspect of ultra-thin sections of virus particles derived from the same suspensions embedded in methacrylate. When examined by this method, the overall structure of the elementary bodies appeared the same independent of the mode of fixation (Figs. 4 and 5). This seemed to prove that the essential morphological details of this material have not been changed artificially by fixation in ethanol–acetic acid, which has been used extensively in our work with enzymes. A schematic drawing (Fig. 6) demonstrates our present knowledge.

The double contour of the surrounding membrane already discerned by Morgan *et al.*[7] in extracellular virus particles was best demonstrated after fixation with buffered osmic acid and less clearly with buffered formaldehyde. Pretreatment with ethanol–acetic acid, however, produced only a single contour. The membrane enclosed different structures. The most impressive picture was gained from vertical trans-sections (Figs. 4*a* and 5*a*). A rectangular core with rounded edges was found surrounded by a rim of high opacity and with an area of lower density at the centre. Oval, bar- or dumbbell-shaped outlines were observed, as previously described in connexion with vaccinia, fowl pox, ectromelia and molluscum contagiosum[7-9]. In horizontal sections (Figs. 4*b* and 5*b*) this material occupied the central spaces of the particles, its outlines following the outer membrane. This core appears to be identical with the nucleus-like annular body, which evidently contains deoxyribonucleic acid and protein, as shown in our studies with enzymes. Within this core and situated at the four corners distinct opaque round bodies were seen, measuring 5–12 mμ in diameter. These structures, which are omitted in the diagram in Fig. 6, are supposed to indicate the satellite bodies of untreated elementary bodies, first described by Green *et al.*[10]. In sections fixed by osmic acid the core containing deoxyribonucleic acid was often surrounded by a double-lined membranous structure, measuring about 15 mμ in total thickness (Fig. 4*b*). This structure was less frequently observed after formaldehyde and seldom after ethanol–acetic acid treatment. It is suggested that this structure which separates the core from an outer layer is possibly related to a nuclear membrane.

The outer layer with a thickness of about 20–25 mμ followed the outlines of the core. It was filled with a homogeneous material of moderate electron-optical density. This material appears to be identical with the peripheral protein part of the virus which, in contrast to the core containing deoxyribonucleic acid, is hydrolysed by pepsin, or by papain at acid reaction. Up to now there is no indication of the presence of nucleic acid in this zone. In its exterior part this material is in contact with the enclosing membrane. In the central region, however, two bodies of equal size are arranged in spaces between the protein layer and the outer membrane, thus producing the central elevation previously seen in shadowed untreated particles[5]. A connexion between these two bodies is still questionable. It is suggested that this material represents the enzymatically disclosed central structure which is resolved into two separated bodies in vertically prepared virus particles. The chemical nature of these bodies obviously is subject to variation. The susceptibility to protease digestion points towards a protein constituent which seems to be more or less protected against digestion in different elementary bodies of the same suspension.



a *b*

Fig. 5. Sectioned elementary bodies, fixed in ethanol–acetic acid (2 hr.), methacrylate-imbedded, prepared on carbon film (× 130,000). *a*, Vertical section ; *b*, horizontal section

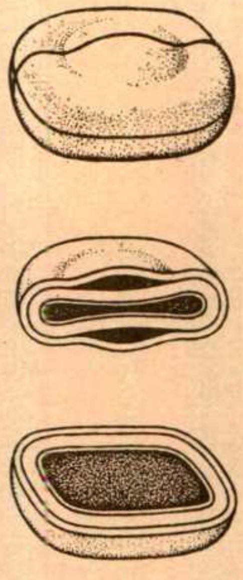


Fig. 6. Schematic drawing showing vertical and horizontal trans-sections (× *c*. 90,000)

A comparison of these results demonstrates that all morphological details disclosed by enzymes could also be identified in sectioned material. Further support for the correctness of the concept was gained from particles prepared by the critical point method[6]. Using 100 kV., it was possible to penetrate the vertically attached particles so far that diffuse inner structures could be observed. These corresponded to the outlines seen in vertical sections (Fig. 1), since a dumbbell-like opaque core surrounded by a zone of lower density could be discerned.

It is important to point out that these results apply only to a stage of virus development which predominates in suspensions after differential centrifugation. Working on infected tissue, Morgan *et al.*[7], and later Flewett[11], differentiated between an intracytoplasmic form of particle, enclosed by a single membrane, and another one found near the surface of the host cell and in extracellular spaces, which is characterized by a double membrane. The latter one seems to be identical with the stage described in this work. Since we know that elementary bodies of this type prevail in suspensions which retain infectivity for a long time, it seems reasonable to interpret these particles as resting ones.

Details will be published elsewhere. This work was supported by grants from the Deutsche Forschungsgemeinschaft. The technical assistance of Rudolf Geister is gratefully acknowledged.

Excitation of Luminescence in Gases by 2–4 keV. Lithium Ions

THE excitation of part of the auroral spectrum by the passage of fast protons from the Sun through the upper atmosphere[1], together with recent applications in nuclear physics of gaseous scintillators[2] for the detection of heavy particles, has made the excitation of luminescence in gases by heavy particles one of increasing interest and importance. While a reasonable lower limit on the rate of excitation is the rate of ion-pair production[3,4], detailed information is not generally available on excitation processes and on the spectral character of the resulting radiation. The purpose of this communication is therefore briefly to report upon some experiments in which 2–4 keV. lithium ions (Li^+) were employed to excite luminescence in nitrogen, oxygen, argon and air, and to compare the spectral composition of the luminescence with that reported by other workers who have used faster particles[5,6].

A thermionic ion source, with a lithium aluminium silicate-coated anode, was designed, with the aid of a rubber-sheet gravity analogue, and constructed. The source produced a collimated ribbon-like beam of lithium ions which was used to bombard nitrogen, oxygen, argon and air over a pressure-range of 5–40 microns mercury and over an energy-range of 2–4 keV. The luminosity produced in the gases by the ion beam was observed spectrographically (both along and perpendicular to the beam) and photographed at a camera aperture of $f/2$ and at a reciprocal dispersion of 130 A./mm. at λ 4000 A. and 1400 A./mm. at λ 8000 A. Analysis of the microphotometer traces of the spectra enabled positive identification of the main spectroscopic features to be made. They are summarized in Table 1, together with comparable observations of workers previously cited. More detailed information on our experiments will be published elsewhere shortly.

The strongest spectral features were lines of neutral lithium, together with lines of the neutral and ionized atomic nitrogen in the case of nitrogen, lines of neutral atomic oxygen in the case of oxygen, and of a combination of these features in the case of air. Lines of neutral and ionized argon also appeared in the case of argon. Evidently, the relatively slow collisions between lithium ions and the target nitrogen molecules resulted in (*a*) charge transfer in which the lithium ion captured an electron from the molecule to become an excited lithium atom which radiated, and (*b*) spontaneous dissociation of the resulting molecular ion into excited atomic and ionic components which also radiated:

for example, $Li^+ + N_2 \rightarrow Li^* + N^* + N^{+*}$

$$Li^* \rightarrow Li + h\nu$$
$$N^* \rightarrow N + h\nu$$
$$N^{+*} \rightarrow N^+ + h\nu$$

The absence of lines of ionized atomic oxygen in the case of oxygen may possibly be explained by the predominance of the mechanism: $Li^+ + O_2^- \rightarrow Li^* + O^* + O^*$ over the mechanism $Li^+ + O_2 \rightarrow Li^* + O^* + O^{+*}$. For it is well known that O_2^- ions are readily formed by oxygen in the presence of slow electrons (of which there must have been many in the source) owing to the extremely small electron affinity of the ion.

In contrast to these observations, Carleton[6] excited predominantly bands of N_2^+ and the lines of atomic hydrogen by bombarding nitrogen with protons of 2·5 keV. energy, while Fan and Meinel[5] excited predominantly N_2 bands (together with a few weaker N^+ lines) by bombarding air with a variety of particles (H^+, D^+, He^+, Ne^+) at higher energies. They also observed N_2 bands which were attributed to secondary excitation processes associated with electrons. In these experiments, charge transfer without dissociation was assumed to be a predominant mechanism. Evidently there was a negligible change in the molecular internuclear separation during the collision. Thus a change in only the electronic configuration of the molecule resulted. On the other hand, in our experiments the collision time was not negligible compared to the period of internuclear vibration. A sufficiently violent perturbation of the internuclear motion resulted as to cause dissociation as well as electronic excitation. The influence of collision time, measured by the parameter $f = (2M/V)^{1/2}$, is seen in Table 1. f measures the number of half-periods of internuclear vibration during which the ion crosses the molecular diameter. (M is the

Table 1

* Note the absence of He I and Ne I lines was ascribed by Fan and Meinel (see ref. 5) to the formation of these atoms in their ground-state by the charge transfer process.

ionic mass in atomic weight units, and V is the ionic energy in eV.). When $f \sim 0{\cdot}1$, dissociation and charge transfer predominate, and a predictable atomic spectrum results; while when $0{\cdot}01 < f < 0{\cdot}001$, charge transfer alone results, and the predominant spectrum of the molecular ion and the neutralized atomic ion is seen.

In the experiments of Huggins[5] and of Ortner and Salim[5], spectra of the luminescence produced in air by very energetic α-particles from radioactive sources were reported. Here $f \sim 0{\cdot}001$ and the predominant primary radiation appeared to be the N_2^+ bands, and a few N^+ lines. Bands of N_2 were also observed which were probably due to secondary excitation from the energetic electrons produced in the ion-pair production along α-particle tracks. It should therefore be possible to predict the rough spectral composition of the scintillations produced in monatomic and diatomic gases by energetic fast particles from a knowledge of ion energy, gas composition, energy-levels of significant atoms, molecules and ions involved, and a rough idea of the relative oscillator strengths of the possible radiative transitions. Spectroscopic studies of such scintillations are in progress.

Radon Content of the Air

In recent years it has become a practice to deduce the radioactivity of the air (that is, its radon content) from the sampling and measurement of the short-lived radon daughter products. This method dates from the beginning of the present century[1]. The unique difference between the early measurements and the recent ones consists in the method of sampling the active deposit of radon; while nowadays deposition on filter paper is almost exclusively used, in the early experiments the transmutation products of radon were collected on the electrode by a strong electric field.

As for the filter-paper method, it has been shown by Harley[2] that even a molecular filter does not retain all airborne dust particles of submicroscopic size. On the other hand, the experimental results of Wilkening[3] indicate that most of the natural radioactivity in the atmosphere attaches itself to particles having diameters of 0·001–0·04 micron, and that a predominant grouping of the activity occurs in the vicinity of two particle diameters, namely, 0·009 and 0·018 micron. Hence it is not surprising that the radon values for the atmosphere as deduced from the filter paper method are too low. Thus Dawson[4] finds for January 1950 and on the roof of St. Bartholomew's Hospital in London a mean value of $0{\cdot}94 \times 10^{-16}$ curie radon/ml., and for May of the same year $0{\cdot}28 \times 10^{-16}$ curie radon/ml. Dawson's values were used very recently[5] as representative of the radioactivity of London's atmosphere. Anderson *et al.*[6] have found by the filter-paper method on the roof of the Physics Department of the Royal Cancer Hospital in London on sunny dry days values as low as $0{\cdot}02 \times 10^{-16}$ curie radon/ml.; but by comparing the filter-paper measurements to the direct determination of radon content of the air by the ionization method, they find that filter-paper values correspond only to 2–3 per cent of the true value of radon content. It is evident that in the free atmosphere radon is not in equilibrium with its daughter products and that variable fractions of the whole amount of the active deposit are attached to the dust or smoke particles and can be collected by the filter paper. We have found the same results for the radon content in closed rooms.

The experiments were carried out in a laboratory where concentrated radon solutions are prepared. The volume of the air in this laboratory is 39 m³. Air samples were examined simultaneously by the Schleicher–Schüll 589 filter-paper and in ionization chambers calibrated by a radium standard solution. About 140 litres of air were drawn during 15 min. with an average speed of 9·3 litre/min. through the filter paper, which was afterwards rolled on a Geiger–Müller tube with glass walls penetrable to β-rays with energy greater than 0·5 MeV. An interval of 10 min. was also allowed between the end of the air sampling and the first counts. Measurement of the active deposit was usually prolonged to 2 hr. The curves obtained correspond almost exactly to the equilibrium of radium A, B and C during the time of air sampling. The results of four sets of experiments are summarized in Table 1.

Table 1

10^{-9} curie/litre	N (counts/min.)	N^* (counts/min.)
1·40 ± 15 per cent	25,690	18,350
0·59 ± 10 ,,	7,060	11,980
2·80 ± 10 ,,	48,000	17,150
1·30 ± 15 ,,	12,790	9,830

The first column gives the content of radon determined by direct ionization measurement, the second the number N of counts 10 min. after the end of the sampling of the active deposit on the filter paper, and the third the values of the second column reduced to the content of 1×10^{-9} curie/litre and designated by N^*. From the values of N^*, it is clear that even in closed rooms there is no constant ratio between the active deposit collected on the filter paper and the radon content of the air. From these experiments and the results of Anderson *et al.*[6], it is evident that there is no reason for assuming this ratio to be a constant equal to or less than 1, as is frequently done.

Spectroscopic Indications of an Internal Spiral Arm in the Galaxy

SPIRAL structure within our galaxy has been detected by three methods: (*a*) space-plotting of stellar associations[1], (*b*) multiple structure in the *H* 21 cm. radiation[2], (*c*) multiple structure in the interstellar lines of Ca II and Na I in distant stars[3]. The radio method (*b*) has the advantage over the two optical methods in that it will penetrate to the limits of the galaxy. On the other hand, the interpretation of the radio profiles for directions within 90° of the galactic centre is greatly complicated by the superposition of radiation from regions at very different distances which have the same angular velocity. By contrast, method (*c*) can reveal unambiguously the presence of one, two or more spiral arms within a light-path limited by a distant star. The limited light-paths used in method (*c*) are of advantage in the internal regions of the galaxy.

In the course of work at the Radcliffe Observatory on velocities of southern *B* stars, certain stars with distances probably greater than 3 k.parsecs were selected for study at a dispersion of 19 A./mm. at 3933 A., with the view of possible resolution of the interstellar *K* line into components due to spiral arms. Among the five stars listed below, three have been found to have two well-separated *K* lines, whereas in the other two *K* is seen to be resolved with a separation which cannot be reliably measured but which is of order 25 km./s.

Stars with double *K* line

HD	m_v	*l*	*b*	Velocities (km./s.)		
				Star	K_1	K_2
142,468	8·1	295·6	− 1·8	− 40	− 14	− 84:
142,565	9·0	295 7	− 1·8	− 25	− 12	− 75
147,331	8·9	299·8	− 3 0			
148,546	7·8	311·1	+ 5·9			
173,987	9·0	354·6	− 3·7	+ 54:	+ 1:	+ 43:

Four stars in the longitude range 273°–289°, namely, *HD* 114,340, 122,324, 125,241, 136,239, have also been examined with the same dispersion but failed to show doubling of the interstellar lines, despite the fact that these stars are probably as distant as those with double lines and lie in longitudes more favourable for resolving components due to differential galactic rotation.

Of the five tabulated stars with double *K*, four lie south of the galactic centre. In each case the low-velocity component must correspond largely to the Sagittarius arm. The high-velocity component presumably corresponds to an interior arm which might be called the Scutum-Norma arm from the constellations in which it is probably seen tangentially. The radio work has already indicated that this arm is seen tangentially in longitude 3° at a distance of about 5 k.parsecs from the centre[4]. No details concerning radio observations at longitude 295° seem to be available at present[5].

The negative evidence from the four stars with $l = 273°–289°$ (some of which have been suggested by E. Smith[6] as belonging to a distant arm) might be taken as supporting the view that the Scutum-Norma arm does not extend beyond 290°. However, these stars might lie on the near side of the arm behind an undetectably small amount of the gas associated with the arm.

The observed *K* velocities in the three stars *HD* 142,468, 142,565 and 173,987 can be used to derive $\Delta\omega(R)$ on the assumption of circular motions. The calculations are rather sensitive to the assumed longitude of the galactic centre and to the corrections for solar motion. But if the standard values are assumed, we find a value of 3·5 km./s./k.parsec for the low-velocity components (consistent with the predictions of the radio model for the combined effects of the Sagittarius arm and of gas still nearer the Sun) and for the high-velocity components 16 ± 3 km./s./k.parsec in agreement with the model for the more distant arm suggested by the radio observations at $l = 3°$. It is difficult to avoid the conclusion from these observations that in the Scutum-Norma arm the value of $\Delta\omega(R)$ is greater at $l = 295°$ than at $l = 355°$. Interpreted literally, this would imply that the Norma branch is nearer than the Scutum branch to the centre of the galaxy, that is, that this arm is opening out in the direction of rotation. It would be weighting the meagre data too heavily to deduce that this is a property of the arm as a whole. A more plausible suggestion is that in front of the two stars *HD* 142,468, 142,565 we are observing a peculiar stream motion of the Ca II gas.

Radioactive Sulphur produced by Cosmic Rays in Rain Water

ISOTOPES of carbon, hydrogen and beryllium arising from interactions of primary and secondary cosmic-ray particles with the oxygen and nitrogen nuclei of the atmosphere have been recorded[1]. Two isotopes of phosphorus due to spallation of atmospheric argon have also been found[2]. We can now add to the list sulphur-35.

Sulphur-35 is a beta-emitter ($E_{\text{max.}} = 167$ keV.) with a half-life of 87 days. Because of the low decay-energy, self-absorption of electrons is serious and it is necessary for detection to have samples of high specific activity. As is well known[3], rain water often contains appreciable amounts of stable sulphur partly due to ocean spray, and partly to industrial contamination. Samples collected in Bombay have, on the average, large amounts of stable sulphur (about 0·7 mgm. per litre). In order to reduce such contamination and thereby obtain samples with higher specific activity, we have used rain water from Banaras and from Kodaikanal. In samples from Banaras, which is far distant from the sea, the sulphur contents were low, although still about 0·27 mgm per litre, and detection was comparatively easy. Further improvement was achieved by obtaining a sample from Kodaikanal, which is well inland, 7,500 ft. above sea-level and with much less industrial pollution. This sample contained 0·08 mgm. of sulphur per litre. The results for all the samples are given in Table 1. Since our counter is not yet calibrated for soft beta-radiation, the absolute number of atoms may be in error by as much as a factor of two. The counts per hour have been converted into disintegrations/min. and atoms per litre, by taking account of counter geometry, window absorption, self-absorption, estimated chemical efficiency and decay.

Table 1

Sample	*V*1	*V*2	*V*3	*K*1
Place	Banaras	Banaras	Banaras	Kodaikanal
Date of rainfall	22.7.56	23.7.56	25.7 56	19.8.56
Size of sample (litres)	185	118	300	150
Total sulphur content (mgm.) (calculated from $BaSO_4$ precipitate)	53·2	51 8	71 4	12 2
Sulphur deposited for counting (mgm.)	11·4	2·2	5·4	3 2
Counts per hr. (above background)	64±8	85±9	74±7	75±11·5
Disintegrations/min. per litre	0 8	6·5	1·35	0·55
Atoms of sulphur-35 per c.c. of water	145	1,175	244	100

To extract sulphate from rain water we employed ion exchange columns containing the anionic resin, 'Amberlite *IRA*-400', in chloride form. Sulphate was precipitated as barium sulphate from the eluate. The barium sulphate was heated in a stream of hydrogen[4] and the hydrogen sulphide evolved was bubbled through ammoniacal water; sulphur was recovered from it, as a pale yellow precipitate, by adding dilute nitric acid. This sulphur was deposited on a 1-in. diameter brass holder by sublimation and counted on a heavily shielded end-window counter which is surrounded by rings of anticoincidence counters. The background of the counter was 62 ± 2 counts per hour.

To ascertain the nature of the activity, transmission measurements were made for each one of the samples by using aluminium absorbers of different thickness. The results, with their statistical errors, are shown in Fig. 1. All the samples give absorption spectra identical with that of artificial sulphur-35 in the same geometry.

Further purification of sample *V*1 by sublimation showed no change in specific activity. The values, corrected for self-absorption, were 7·3 ± 0·8 counts per hr. per mgm. before, and 7·7 ± 0·9 counts per hr. per mgm. after, resublimation.

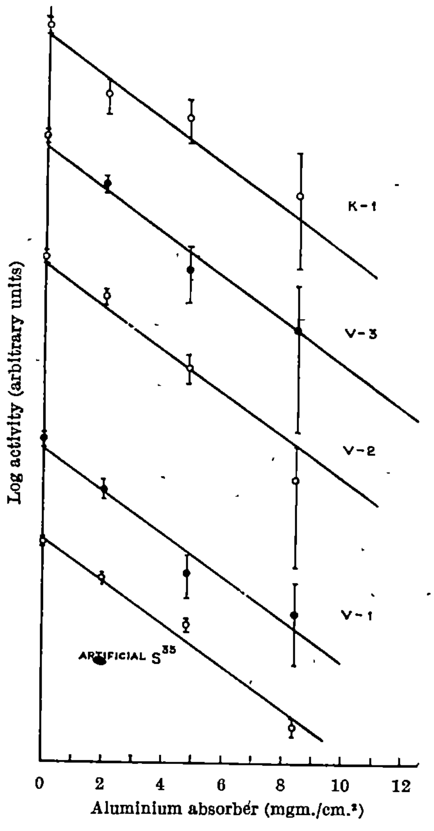

Fig. 1. Absorption spectra of sulphur samples

In order to test the chemicals and equipment for possible contamination, a reagent blank was prepared by precipitating sulphate ions of dilute sulphuric acid as barium sulphate and reducing it to sulphur in the same apparatus. No activity was found.

Since the activity is obtained after a chemical procedure highly specific for sulphur and the beta-ray absorption spectrum is identical with that of artificial sulphur-35, we conclude that the activity is due to that isotope.

The mean concentration of 1·9 disintegrations/min. per litre for sulphur-35 obtained here is comparable to the value of 1·4 obtained for phosphorus-32 by Lal *et al.*[2]. This is to be expected if the isotope is produced by cosmic radiation in atmospheric argon in the same way as phosphorus-32. However, the possibility that some of the activity is due to sulphur-35 produced by nuclear explosions cannot be ruled out. In order to check on possible contamination by such explosions, long-term observations are needed.

I am much indebted to Prof. B. Peters for his interest and many suggestions during this work. I thank also Mr. N. Narasappaya for help in counting the samples, and Dr. G. K. Das, Physics Department, Banaras Hindu University, and Mr. T. S. G. Sastry, of the Physical Research Laboratory, Ahmedabad, for their co-operation in collecting the samples from Banaras and Kodaikanal respectively.

Rate of Transformation of Rhombohedral Graphite at High Temperatures

The hexagonal modification of graphite (common graphite) is composed of identical layers of stacking sequence *ABAB* . . . , while in the rhombohedral modification the sequence is *ABCABC* . . . , the latter modification being confirmed by Lipson and Stokes[1]. The occurrence of this modification and the enhancement and weakening of the X-ray diffraction lines belonging to it by chemical, mechanical and thermal treatments have been described by Hofmann[2], who states that it is transformed to the hexagonal modification in a graphitizing oven in an atmosphere of carbon monoxide at 3,000° C. In the course of experiments on the thermal expansion of graphite by X-ray diffraction[3], I observed that the corresponding lines were markedly weaker at much lower temperatures *in vacuo*. The rates of transformation were measured using the following improvements in technique. (1) Plate specimens were used in place of rods; to achieve a definite degree of orientation of crystals, 21 mgm. of powder of Ceylon graphite of average diameter 0·05 mm., purified with hydrochloric and hydrofluoric acids, was compressed to a plate 0·5 mm. thick and 6 mm. in diameter with a

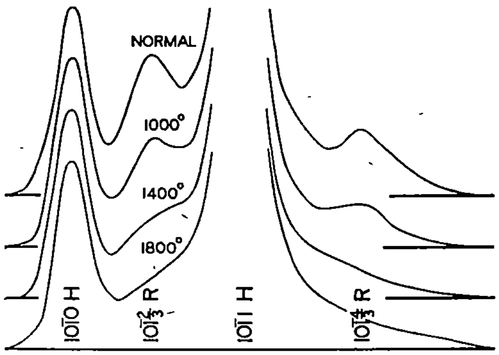

Fig. 1

pressure of 40 kgm. without adding any adhesive substances. (2) The plate was mounted on a Debye–Scherrer camera 20 cm. in diameter so as to bisect the angle between the incident and diffracted rays and oscillated about this angle with a half-amplitude of 30°. (3) Since, with cobalt K-radiation, the curvatures of the diffraction lines were not large, a stepped absorber made by piling aluminium foils was placed in front of the photographic film so that the blackening of each line was graded by known ratios, permitting more accurate determination of the intensities than by the use of intensity marks photographed on one side of a film.

The heat treatments of the specimen plates were performed at 1,000°, 1,200°, 1,400°, 1,500°, 1,600°, 1,700° and 1,800° C. and for 20 min., 1 hr., 3 hr. and 10 hr. Use was made of a small resistance furnace consisting of a Ringsdorff carbon tube just permitting the insertion of the plate, and evacuated with an oil diffusion pump backed by a booster pump. Before use the furnace was run at a temperature of 1,800° C. for 10 hr. For each heating-cycle no fluorescence was observed in a discharge tube for vacuum testing after several minutes.

The intensity curves of the diffraction patterns obtained with the specimens heated for 1 hr. are shown in Fig. 1, where scales are reduced to the true intensity. The integrated intensities of the 10$\bar{1}\frac{2}{3}$ line of the rhombohedral graphite were estimated from these curves and the percentages of the original content are plotted against temperature in Fig. 2. It will be seen that the decrease is linear in the observed range. An attempt was also made to obtain the rate of isothermal transformation as a function of time by the decreases of intensity of the line, but the dependence on time was found to be smaller than that on temperature, and the accuracy of the intensity measurements was not large enough for a definite trend to be determined.

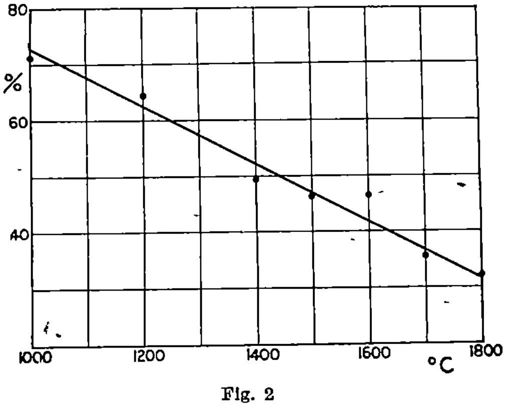

Fig. 2

With Madagascar graphite flakes of 0·5–1 mm. diameter similar results were obtained.

Dielectric Properties of Solid Alkyl Polymethacrylates

WE have investigated the dielectric properties of methyl-, ethyl-, *n*-butyl- and *iso*butyl-polymethacrylates in the solid state, at temperatures ranging from − 30° C. to + 150° C., that is to say, above and below the transition temperature T_g from the glassy to the rubbery state. We have measured the dielectric constants and losses at frequencies varying from 500 c./sec. to 14 Mc./sec., by means of a special Scherring bridge up to 500 kc./sec. and a twin T apparatus for the higher frequencies.

With the methyl-polymethacrylate we confirmed the results obtained by Deutsch, Wolf and Reddish[1]: the dielectric dispersion appears below the glass temperature T_g and is prolonged through the transition temperature without any discontinuity.

With the ethyl, *n*-butyl and *iso*butyl compounds, the dielectric dispersion appears in the transition region. Above T_g, the critical frequency f_c corresponding to the maximum value ε_m'' of dielectric losses was of the order of a few kilocycles/sec. and could be detected with our apparatus. If the dispersion exists below T_g, the critical frequencies must be much lower than 500 c./sec.

By plotting log f_c as a function of $1/T$, straight lines were obtained. The activation energies ΔH calculated from the slopes of these straight lines were considerably lower than the apparent activation energies ΔH_a determined by the Williams, Landell, Ferry equation[2], as can be seen from Table 1.

Table 1. ACTIVATION ENERGIES FOR DIELECTRIC PROPERTIES

Alkyl group	Glass temperature	ΔH (in k.cal.)	ΔH_a ($T = T_g + 50°$) (in k.cal.)
Methyl	105° C.	23	73
Ethyl	47° C.	24	55
n-Butyl	17° C.	30	46
*Iso*butyl	67° C	43	61

Moreover, as the temperature is raised, the shape of the dispersion curve changes; a narrowing of the reduced dielectric losses curves ($\varepsilon''/\varepsilon_m''$ against log f) is found.

The dielectric dispersion appearing above T_g for ethyl-, *n*-butyl- and *iso*butyl-polymethacrylates must therefore not be considered as a primary dispersion region. It is probably due to an electrically dominant secondary mechanism, presumably the orientation of the dipolar side groups independently of the main polymer chain.

These results will be published in detail elsewhere.

I wish to acknowledge my indebtedness to Prof. L. de Brouckère, under whose supervision this work was carried out.

Conductance of Concentrated Solutions of Strong Electrolytes

Numerous attempts have been made to extend the Debye–Huckel theory to electrolyte solutions of higher concentrations than 0·1 *N*. The attempts of Falkenhagen and Leist[1], Robinson and Stokes[2], Wishaw and Stokes[3], and Leist[4], are the most notable contributions in recent times in this direction.

Based on thermodynamical reasoning, we have evolved a new concept of 'concentration potential' (C_p) of an electrolyte solution, which may be defined as the ratio of moles of the electrolyte per 1,000 gm. of water at a given molality to the moles of the electrolyte per 1,000 gm water at saturation at the same temperature. The 'concentration potential' at any molality other than at saturation, being a fraction, may be visualized as representing in magnitude by the same fraction as the sum total of the effects due to hydration, ion-solvent interaction, quantum-mechanical forces of attraction, ion-pair formation, dielectric constant, etc., which tend to a limit at saturation. I. Bencowitz[5] found empirically that by using the ratio of any molality of an electrolyte solution to that at saturation, which he called the 'degree of saturation', instead of the molal concentration, vapour pressure lowerings even at high concentrations were explained by simpler relationships.

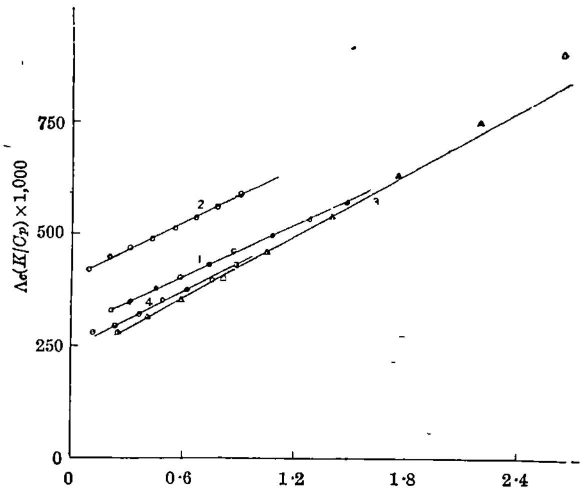
Similarly, we have introduced a new viscosity term, potential viscosity (η_p), which may be defined as the ratio of the viscosity of the electrolyte solution of a given molality to that at saturation at the same temperature.

Applying these new concepts, we have formulated the equation:

$$\Lambda_c = \Lambda_s + A\,(1 - C_p)/\eta_p \qquad (1)$$

where Λ_c is the specific conductance $K \times 1{,}000/C_p$. Hence, Λ_s is specific conductance at saturation $K_s \times 1{,}000$.

C_p and η_p have been defined above and A is a constant the properties of which have to be elucidated. The proportionality of Λ_c with $(1 - C_p)$ is introduced for the following main reasons. At saturation, $C_p = 1$. At concentrations other than at saturation, C_p is a fraction which may be assumed to be the same as that of the sum total of the internal effects at saturation. Since the equivalent conductance decreases progressively as the concentration increases towards saturation, Λ_c at any molality must be proportional to the 'concentration potential difference' between the concentration potential at the particular molality (C_p) and that at saturation (unity). Λ_c at any molality is therefore proportional to the concentration potential difference at that molality. At infinite dilution the concentration potential difference will be a maximum and therefore Λ_c at infinite dilution will be a maximum. The concentration potential difference at saturation will be zero and therefore the conductance Λ_s at saturation must be a minimum. These results agree with experiment.



1, Sodium chloride; 2, potassium chloride; 3, sodium nitrate; 4, potassium nitrate

The important part played by viscosity at higher concentrations was brought out by Wishaw and Stokes[3]. Though various workers observed qualitatively that conductance varies inversely as the bulk viscosity, there has been no agreement regarding a quantitative formulation of the relationship. Since the non-thermodynamic property viscosity tends to a maximum at saturation, we believe that conductance variation may be assumed to be related inversely to the ratio of viscosity at any molality to that at saturation. The relative viscosity of a solution hitherto considered has been that relative to the solvent. An expanded form of equation (1) will indicate that Λ_c at infinite dilution tends to a constant.

We have measured the conductance and viscosity of aqueous solutions ranging from 1·00 molal to about the saturation concentration at temperatures of 30°, 35°, 40°, 45°, 50° and 55° C. for potassium chloride and nitrate, and sodium chloride and nitrate. At all temperatures for the above electrolytes, a plot of Λ_c against $(1 - C_p)/\eta_p$ was found to be linear. Results obtained at 30° are represented in Fig. 1. A plot of Λ_c against temperature gave perfectly straight lines at all concentrations for solutions of sodium chloride and nitrate, and potassium chloride. Only for potassium nitrate solutions were non-linear curves each forming part of a parabola obtained. The parameter A is a function of temperature.

A detailed account of this work will be reported elsewhere.

Thermal Conduction and Gas Analysis

GAS analysis based on thermal conduction was first introduced by Daynes and Shakespear[1] and depends on the principle that the thermal conduction loss in a particular mixture depends uniquely upon the composition of the mixture, and consequently, if we know the conductivity, the composition can be determined. Since then this principle has been utilized by a number of workers to analyse both the steady state and also the approach to steady state of non-uniform gas mixtures under various conditions. Unfortunately, the procedure adopted has not always been free from objections, and in the present report I propose to discuss the use of a thermal conductivity apparatus for which the theory is now completely understood and the various corrections are exactly calculable. The general design of the thermal conductivity cell is based on the conventional hot-wire type of cell introduced by Kannuluik and Martin[2] and since then has been widely used by a number of workers. Two simple designs for the construction of such cells have been recently made by Srivastava and Saxena[3].

Until now most workers have used this thermal conductivity apparatus more or less in an empirical fashion and obtained calibration curves in terms of galvanometer deflexions against concentration when the same current is passed through the helix of the conductivity cell. This procedure involves several discrepancies as the galvanometer deflexion does not give directly the thermal conductivity, though the latter depends uniquely upon the composition alone. This calibration for a particular gas mixture is correct only at the actual experimental points, and any interpolation is subject to errors arising out of the different accommodation coefficients, wall effects and convection effects with varying composition of the mixture unless the katharometer is so designed as to eliminate or correct precisely for the above effects. The theory of the hot-wire cell using a thick wire has been given by Kannuluik and Martin[2] and seems now to be complete. The corrections to be usually applied in a hot-wire type of apparatus are: (*a*) convection effects; (*b*) wall effects; (*c*) radiation correction; (*d*) radial flow correction; (*e*) the temperature jump correction. The conductivity cells used by us[3] were found to be free from convection and had a negligible temperature jump effect for a considerable range of pressures (6–20 cm. of mercury). We have therefore taken the observations at a pressure of 10 cm. of mercury. For our metal body cells, calculations showed that the wall effect is of the order of 0·01 per cent for gases like helium and neon while for gases of low thermal conductivity like argon, krypton and xenon, etc., the correction is negligible. The correction due to radiation amounts to the reduction in the conductivity value by a fixed amount and is independent of the nature and composition of the gases. The radial flow correction for a given cell and for a fixed value of the current uniquely depends upon the value of the conductivity and therefore upon ($R - R_0$) approximately. Here R represents the resistance of the cell wire for a certain current I, and R_0 for zero current.

In view of the above remarks about the corrections to be applied to the conductivity values measured by a hot-wire cell, it follows from the theory of Kannuluik and Martin[2] that for a given mixture the change in resistance $R - R_0$ of the cell wire will depend uniquely upon the composition of the mixture provided the same current is passed through the cell wire. Consequently, if we first perform an experiment with a mixture of known composition and plot a graph of $R - R_0$ versus composition of the mixture for practically a fixed value of the current, then we can use these plots to find the unknown composition from a knowledge of $R - R_0$ only.

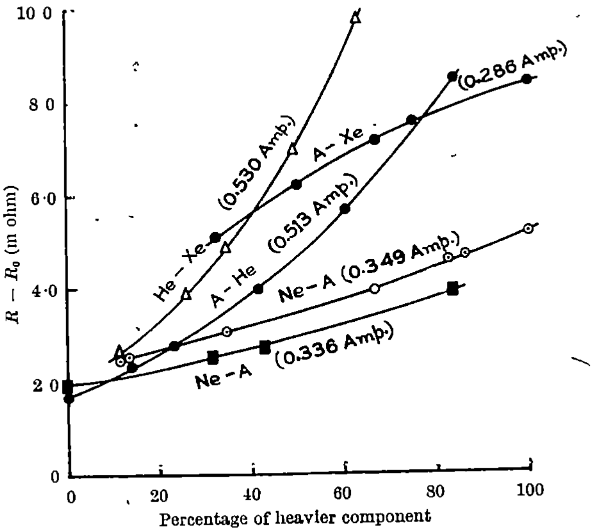

Fig. 1. Plots of $R - R_0$ vs. composition for some inert gas mixtures

Srivastava and Saxena[3] and Saxena[4] have recently obtained results of this type for a number of inert gas mixtures and utilized it to calculate the thermal conductivity. In Fig. 1 are shown the plots of $R - R_0$ versus composition for some mixtures. The experimental currents to which the data refer are recorded for each curve within brackets. These plots can now be utilized with fair accuracy for the purpose of gas analysis.

I am grateful to Prof. B. N. Srivastava for his kind interest and supervision throughout the progress of the work presented here and to the Council of Scientific and Industrial Research, New Delhi, for financial support.

Free Radical Salts of Halogenated Quinones

IT has been shown[1] that bi-radical molecular compounds can be formed from quinones (O—*Q*—O) and aromatic diamines (*D*), and that these compounds are of the ionic form O—*Q*—O]$^-$*D*$^+$.

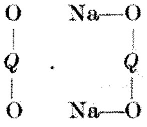
Highly electropositive aromatic diamines can form stable solid paramagnetic salts with simple anions[2], for example, the perchlorate of Wurster's ion, $(CH_3)_2$ N—⬡—N$(CH_3)_2]^+$ ClO_4^-, and it was interesting to see if there also existed stable salts of quinones with simple cations:

$$O—Q—O]^{-}Na^{+}$$

(I)

These should also be free radicals.

As long ago as 1912, Torrey and Hunter[3] studied the highly coloured salts produced by the reaction of tetrahalogenated quinones with sodium iodide. They showed that these solids contain one sodium atom per quinone molecule and they postulated the structure



$$\begin{array}{ccc} O & & Na—O \\ | & & | \\ Q & \cdot & Q \\ | & & | \\ O & & Na—O \end{array}$$

(II)

It seemed to us, however, that such a structure is improbable and that the product of their reaction is more likely to be, instead of (II), the simple salt of the semiquinone (I). The latter has an odd number of electrons and should therefore be paramagnetic.

We have tested four of Torrey and Hunter's coloured substances for paramagnetism by means of the paramagnetic resonance method[4]. The measurements were made at a wave-length of 3 cm. on powdered samples at 90° K. The substances (Table 1) all showed paramagnetic resonance with a single line a few gauss wide and g-value nearly equal to the free electron value. Such resonance is typical of a free radical.

Table 1

	g-value	Line-width (gauss)
Sodium tetrachloro p-quinone	$2·0044 \pm 0·0008$	10
Sodium tetrabromo p-quinone	$2·0068 \pm 0·001$	20
Sodium 2 : 6 dichloro 3 : 5 dibromo quinone	$2·0063 \pm 0·0007$	20
Sodium tetrabromo o-quinone	$2·0077 \pm 0·0008$	30

These results indicate that, as we have proposed, solid stable free-radical salts of quinones do exist, and that the coloured salts of Torrey and Hunter are of this form.

Surface Structure of Blowholes in Cast Iron

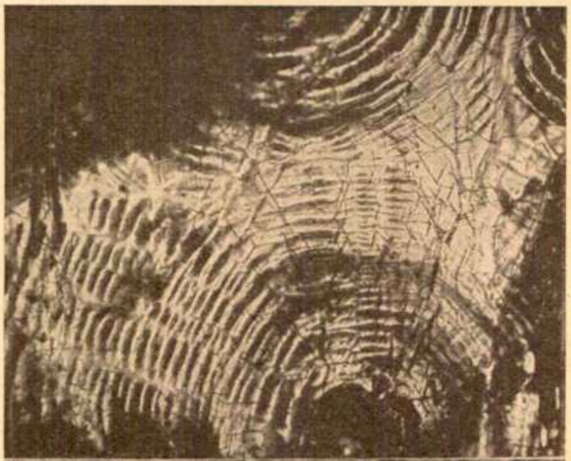
BLOWHOLES caused by evolution of gas are relatively seldom encountered in cast iron. Recently, however, cavities evidently produced by hydrogen gas have been recorded[1-3]. The surface of the blowholes exhibited a peculiar pattern of concentric circular waves or wrinkles. This pattern was imprinted not only on the graphite shell covering the walls of the blowholes but also on the underlying matrix[3]. In the following some complementary observations will be given and a suggestion as to the formation of the structure is advanced.

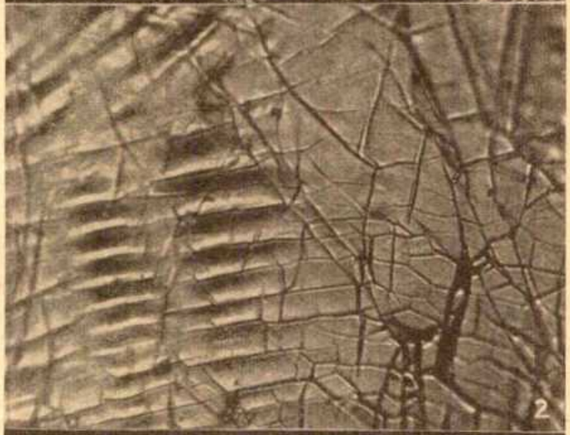
The blowholes examined occurred in cast iron to which magnesium had been added. Water was poured upon the iron in the ladle. The object of this double treatment was to introduce hydrogen into the liquid metal by reaction between the magnesium and the water. It is believed that the blowholes were caused by the evolution of hydrogen or possibly hydrocarbons during cooling. The holes were either approximately spherical or had an elongated shape with the axis perpendicular to the outer surface of the casting. A thin scale or shell of the same metallic material as the matrix, as shown by examination of sections in the microscope, could be removed from the walls of the blowholes.

Fig. 1 shows the surface structure as observed from the interior of a cavity towards the wall. The surface is covered with circular 'waves', seemingly emanating from a few different centres. Within each group of concentric waves there are flat areas with radial extensions. This gives the impression that the groups consist of interfering wave systems with adjacent centres. Closer examination shows (Fig. 2) that the waves can be described as ridges running between U-shaped valleys, as is also seen from polished sections perpendicular to the wall (Fig. 3). On the top of each ridge there runs a marked ditch. Ditches are also seen to traverse the valleys and the flat areas. Sometimes they develop into crack-like formations, sometimes they become more vague. Near the centre of a group of waves the cracks are more pronounced, outlining 'grains' with hexagonal symmetry. In the central part of each wave group there is a pyramid of six-fold symmetry, built up of triangular sectors or 'shields'. The tops of the pyramids are directed towards the interior of the cavities. The shields, which do not fit closely together, have surface markings like arrow-heads pointing towards the top angle.

In a section perpendicular to the wall of the cavity (Fig. 3), the metallic matrix is found to be pearlitic near the wall of the blowhole, changing to a mottled ledeburitic-graphitic cast iron structure in the interior of the metal.

It is tentatively suggested that wrinkles of the kind observed could be produced by compression of a (surface) layer by forces parallel to the surface, the wave crest at any point being perpendicular to the compressive force. The circular form of the wave groups points to common centres from which the forces have radiated. In the central area where the ultimate reason for the deformation should be sought, small cavities, believed to be hydrogen blowholes, were once observed. Evolution of gaseous hydrogen at this position at a stage during cooling when there is a still deformable surface layer around the larger blowhole could well provide the expansion required for the deformation mechanism proposed. Evidence for a secondary evolution of gas is also given by the





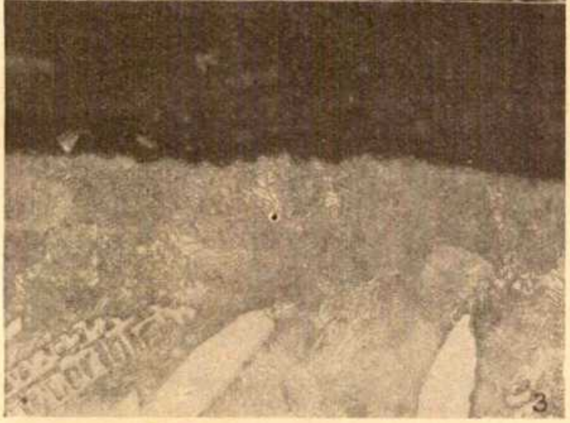


Fig. 1. Surface pattern. × 300
Fig. 2. Surface pattern at higher magnification. × 1100
Fig. 3. Section of blowhole, etched with 'Nital'. × 450

form of the space separating the above-mentioned scale from the main body. As regards the ditches and cracks mentioned above, they are believed to be the result of deformation at a lower temperature where the iron is less ductile.

Polymerization of Tobacco Mosaic Virus from Electric Birefringence Studies

It has been reported[1] that the addition of methylene blue to aqueous solutions of tobacco mosaic virus produces increases in viscosity which can be interpreted in terms of conversion of the monomeric units to end-to-end dimers and possibly higher polymers. The suggestion was made that the association may be the result of interactions between a given methylene blue molecule and sites on the nucleic acid chains of different macromolecules. The production of end-to-end aggregates by an association of this type is in accord with the structural investigations of tobacco mosaic virus[2], which place the nucleic acid at the core of a relatively compact helix. It therefore was of interest to determine whether or not the suggestion of end-to-end aggregate formation by methylene blue could be substantiated independently with a well-characterized monomeric preparation, and by a method particularly sensitive to such aggregates.

Evidence for the presence of rigid end-to-end dimers in some untreated tobacco mosaic virus solutions was found in transient electric birefringence studies[3]. The rotational diffusion constants which are observed in such experiments are greatly decreased upon end-to-end association; for example, by a factor of six upon formation of a tobacco mosaic virus dimer. The experiments reported here were carried out on the preparation designated tobacco mosaic virus I, which was shown to contain no detectable concentration of end-to-end polymers in the previous study[3].

The experimental technique, which involved oscillographic recording of the birefringence transients produced by rectangular pulses, has already been described[3,4]. All solutions were prepared by dilution with distilled water from tobacco mosaic virus I stock[3], which contained 37·5 mgm. of the virus per c.c. and a low concentration of phosphate buffer, of *p*H 7, introduced at an early stage during the preparation.

A solution containing 0·5 mgm. tobacco mosaic virus per c.c. and 10^{-5} *M* methylene blue was allowed to stand for about 15 hr. at 0° C. before warming up to 25° C. for a birefringence measurement. Analysis of the build-up and decay curves gave the same single relaxation time as an untreated preparation (0·5 msec.) within the experimental accuracy ($\sim$ 5–10 per cent). Afterwards, a solution containing 17·7 mgm. tobacco mosaic virus per c.c. and 10^{-2} *M* methylene blue was allowed to stand at 0° C. for 72 hr. before making dilutions, photographing the birefringence transients, and measuring *p*H. The results are summarized in Table 1, which lists the relaxation intervals τ_0, τ_1 and τ_2, in msec. (The term 'interval' is substituted for the formerly used 'time' to reduce the possibility of confusion of $\tau_0, \tau_1, \ldots \tau_i$ (arbitrarily defined[3]) with the relaxation times of the various components.) For the first solution in Table 1 the birefringence did not reach the steady state during the applied pulse, which was of 15 msec. duration. This and the values of τ_0 and τ_1 indicate the presence of species higher than dimers. The conclusion is independent of the particular mode of association since the end-to-end polymers will give longer relaxation times than any other possible forms.

For the second solution, a steady state was approached in about 5 msec. An additional experi-

Table 1

Tobacco mosaic virus conc.	Methylene blue conc.	τ_0	τ_1	τ_2	*p*H
0·5 mgm./c.c.	$2·8 \times 10^{-4}$ *M*	5·0	21·0	—	6·4
0·1 mgm./c.c.	$0·56 \times 10^{-4}$ *M*	0·8	1·0	1·8	6·0

ment with a shorter polarizing pulse (0·7 msec.) was performed, to decrease the contribution from the slower component and permit more accurate evaluation of the relaxation time of the faster component. The two curves for birefringence decay were plotted on semi-log paper and analysed according to the method illustrated in Fig. 5 of a preceding publication[3]. After subtracting the contribution of the slower component, which had a relaxation time of about 3 msec., the remainder exhibited a relaxation time of 0·5 msec. From this it is concluded that the experimental results, at 0·1 mgm./c.c. tobacco mosaic virus and $0·56 \times 10^{-4}$ *M* methylene blue, are adequately explained by the presence of a mixture of monomer and end-to-end dimer[3]. However, the more concentrated solution, obtained from the same sample, consisted of more aggregated species, which confirms the suggestions[1] that the degree of polymerization increases with methylene blue concentration, and that the polymerization is to some extent reversible.

The results are of interest in that they illustrate how the interactions of biological macromolecules and small ions may be studied to determine the location of interacting groups on the macromolecule. Secondly, they suggest a possible cause of the aggregation, which is often troublesome in investigations of the physical chemical properties of such species as tobacco mosaic virus, namely, interaction of a given molecule having two or more cationic sites with negative sites on the nucleic acid chains of different molecules. Although the methylene blue cation carries a single positive charge, it is distributed equally between the substituted amino groups by resonance, so methylene blue molecules may interact simultaneously with two macromolecules. The commonly observed aggregation of tobacco mosaic virus might be caused in a similar manner by multiply charged cations or possibly by partially hydrolysed peptide chains carrying two or more positive charges, and might be prevented by the use of complexing agents. (In a private communication, W. Ginoza has reported that aggregation may be reduced by the use of versene to aid in clarifying the virus during isolation.) Finally, a method for controlling the distribution of lengths of the macromolecular units in a biological preparation offers interesting possibilities for further studies of electric polarization and birefringence in macromolecular systems.

Separation of Oxidized from Non-Oxidized Corticotropin A_1 by Chromatography on Carboxy-Methyl Cellulose

Dedman, Farmer and Morris[1] have shown that corticotropins can be oxidized by hydrogen peroxide to yield products which are inactive in the adrenal ascorbic acid depletion bioassay of Sayers, Sayers and Woodbury[2], and that the biological activity can be completely restored by reduction with thiol compounds. The process is unaccompanied by any change in the amino-acid composition of the corticotropin (Dedman, Farmer and Morris, unpublished observations). Dixon and Stack-Dunne[3] have confirmed this reaction, and have reported a separation of the oxidized and non-oxidized hormones by chromatography on the carboxylic acid cation exchange resin 'Amberlite' *XE*-64 (*IRC*-50).

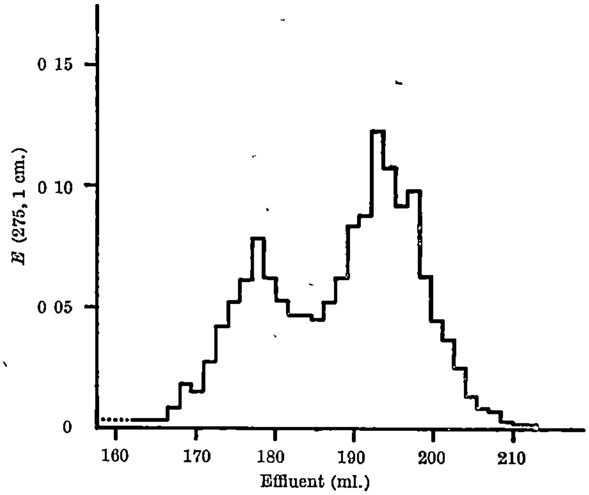

Fig. 1

The present communication describes an alternative chromatographic system for the separation of oxidized and non-oxidized corticotropin A_1, using as the stationary phase carboxy-methyl cellulose prepared by the method of Peterson and Sober[4].

The column was prepared from 1·5 gm. of carboxy-methyl cellulose which had been equilibrated with 0·1 *M* phosphate buffer at *p*H 5·56, and packed under pressure to give final dimensions of 66 cm. × 0·35 cm. A mixture of 1·7 mgm. of corticotropin-A_1 (91 I.U./mgm.) and 1·8 mgm. of corticotropin A_1 oxidized by hydrogen peroxide (27 I.U./mgm.) was dissolved in 0·5 ml. of the phosphate buffer and applied to the column. Development was carried out with 0·1 *M* phosphate buffer, *p*H 5·56, at 19° at a flow-rate of 2·1 ml./hr. 1·5-ml. fractions were collected automatically, and the corticotropin content determined by measurement of the ultra-violet absorption at 275 mμ. The course of the separation is shown in Fig. 1.

Table 1

Material	Treatment	% original A_1 potency
Corticotropin A_1	None	100
Corticotropin A_1	Oxidized with H_2O_2	23 (13–40)
Fraction 1	None	<17
Fraction 1	Reduced with thioglycollic acid, 18 hr., 78°	102 (95–117)
Fraction 2	None	172 (91–300)

The eluate, 171–180 ml., was bulked to give fraction 1, and 186–204 ml. to give fraction 2. The biological potencies of these fractions, together with the potency of fraction 1 after reduction, are given in Table 1. Values in parentheses are fiducial limits of the potencies at $p = 0 \cdot 95$.

It is evident that oxidized corticotropin A_1 forms the faster moving zone (fraction 1) in the chromatogram, and that it can be completely separated from corticotropin A_1 under these experimental conditions. This, together with the earlier separation by Dixon and Stack-Dunne[3], demonstrates that the oxidized form of corticotropin A_1 is a chemically distinct species.

Mutagenicity of Sarkomycin

Since the discovery of Auerbach and Robson[1], various substances have been added to the list of chemical mutagens. It is generally accepted that many strong mutagens have also clear inhibitory actions against neoplasms. It is therefore of special interest to determine whether sarkomycin, an antibiotic with anti-tumour effect, found by Umezawa and his colleagues, has also mutagenic ability. Yamamoto *et al.*[2] and Umezawa *et al.*[3] have shown that sarkomycin induces chromosomal aberrations in Yoshida sarcoma cells and in Ehrlich ascite tumour cells.

Recently, Satô[4] has also pointed out that sarkomycin has a radiomimetic effect upon root tip cells of *Tradescantia paludosa*.

Tests were made on the production of the same mutations which have been used before[5,6]. In the silkworm, *pe* and *re* are located on chromosome V at 0·0 and 31·7, and w_2 on chromosome X at 3·4; all of them control the colour of the egg (and also the colour of the eye). Whereas the normal colour is black, *pe/pe* and w_2/w_2 eggs are white and *re/re* eggs red. Eggs homozygous for both *pe* and *re* are also white (the eye of *pere/pere* is green). The sarkomycin was extracted from *Streptomyces* as the sodium salt and was a viscous syrup light-brown in colour. It was diluted in physiological saline solution for silkworms to a final concentration of 7·5 unit/ml. (unit used here is a special effective value as antibiotic), and the *p*H was adjusted to 6·8 with sodium bicarbonate. 0·05 ml. of this solution was injected into the abdomen of wild male or female moths. 10–60 min. after the injection these moths were mated to double recessive *pere/pere* or w_2/w_2 partners. Eggs from these matings were examined as to egg colour, and the mutation-rates were estimated as the percentages of aberrant eggs in total pigmented eggs.

This method makes it possible not only to deal with many samples but also to compare the results of those obtained with the other chemical mutagens, such as nitrogen mustard or nitromine (Nakao, Y., unpublished data).

Table 1

No. of experiment	Sexes of treated moths	No. of tested eggs (total pigmented eggs)	Aberrant eggs	
			No.	Percentage
C_1		3,333	1	0·030±0·030
C_2	♂	4,074	0	—
1	♂	1,535	6	0·391±0·159
2	♂	4,485	3	0 045±0 032
3	♂	3,364	13	0·386±0·107
4	♂	1,192	4	0·336±0·168
C_3	♀	2,818	3	0·106±0·061
5	♀	1,234	0	—
6	♀	4,629	0	—
C_4	♂	2,636	0	—
C_5	♂	5,045	0	—
7	♂	2,362	3	0·127±0 073

(1) Partners in matings of the first nine are *pere/pere*, and those of the last three (C_4, C_5 and Exp. 7) are w_2/w_2. (2) Doses of sarkomycin are 0·05 ml. of 7·5 unit/mol. solution except Exp. 7 (0 05 ml. of 17·4 unit/ml.). (3) Intervals between the injection and the mating are 10–60 min.

The experiments were repeated several times, and the results have been summarized in Table 1. The mutation-rates in the control series were generally small except in the case of control 3. No aberrant eggs were obtained when the female moths were treated (Exp. 5 and 6). After treatment of males some aberrant eggs occurred in three experiments (Exp. 1, 3 and 4) but not in all. The numbers of aberrant eggs were, however, small and mosaic eggs formed the bulk, as after treatment with nitrogen mustard or nitromine.

Since the spontaneous mutation-rates at the *pe* and *re* loci sometimes reach quite high values (control 3) (Nakao, Y., unpublished data) and the differences between control and experimental rates were small, we used also the w_2 locus in which spontaneous mutation-rate is always low[7] (controls 4 and 5 and exp. 7). The results support the view that sarkomycin has slight mutagenic power for the silkworm.

The variability of the results may be due to the difficulty of obtaining sarkomycin samples of uniform effectiveness by extraction from *Streptomyces erythrochromogenes*.

It is very interesting that substances like sarkomycin produced by a living organism have slight but probably real mutagenic effect. But there have been such precedents. Mustard oil tested by Auerbach and Robson[8] is an example.

We wish to express our sincere gratitude to Dr. C. Auerbach not only for her kind criticisms and advice, but also for her kindness in reading the original manuscript.

Effect of Chloramphenicol in maintaining the Viability of *Escherichia coli*

THERE is ample evidence that cultures of non-sporing bacteria tend to die on prolonged storage. A widely held belief, supported by much less evidence, is that the presence of bacteriostatic antibiotics increases the tendency of bacteria to die. Thus Wilson and Miles[1] state that "... although by definition they [bacteriostatic antibiotics] inhibit growth without killing the cell, they are in fact slowly bactericidal", but the evidence for this statement is conflicting[2–8]. An explanation of this conflict may lie in the finding of Valentine[8] that the tendency of bacteria to die under conditions of bacteriostasis induced by chloramphenicol varies from species to species.

The experimental results given below indicate that under certain conditions of bacteriostasis chloramphenicol, instead of increasing the tendency of *E. coli* to die, has the reverse effect. It may, in fact, prevent bacteria from dying. An analogous situation is presented by the drying of bacteria; slow drying causes death of many species whereas freeze-drying is an accepted way of maintaining viability.

The organism used in the present experiments was *E. coli* (N.C.T.C. 9001), and cells were harvested from 24-hr. cultures in meat extract broth and resuspended in broth or in broth containing chloramphenicol. Total counts were determined by the Spekker absorptiometer calibrated by direct counts in a Petroff–Hausser chamber. Viable counts were determined by a modification of the method of Miles and Misra[9] in which 100 drops instead of 6 of each dilution were taken, giving about a six-fold reduction in the error of estimation. The variables were temperature of incubation and concentration of chloramphenicol. In the first instance experiments were carried out at a low temperature with a high concentration of cells in order to make conditions as inimical as possible to cell multiplication. Later, it was found that the results were more striking when the incubation temperature was raised to 22° C.

It can be seen from Tables 1 and 2 that, instead of hastening the death of bacteria, chloramphenicol may, under the conditions of the experiment, act in such a way that the viability of the culture is maintained. Thus the viable count of the control suspension stored at 5° C. fell to about half its original value by the end of three weeks, whereas in the presence of 10 or 100 μgm. per ml. of chloramphenicol it remained unchanged. When similar suspensions were stored at 22° C. the effect was even more marked. The viable count of the control suspension fell to about one-eighth of its original value within one week, but with 100 μgm. chloramphenicol per ml. it showed only a slight decrease, and with 10 μgm./ml. it was still more than half the original value.

Table 1. CHANGES IN THE TOTAL AND VIABLE COUNTS OF SUSPENSIONS OF *E coli* STORED AT 5° C. IN THE PRESENCE AND ABSENCE OF CHLORAMPHENICOL

Period of storage (days)	Total count cells per ml. × 10^7			Viable count cells per ml. × 10^7		
	Concn. of chloramphenicol μgm. per ml.			Concn. of chloramphenicol μgm. per ml.		
	0	10	100	0	10	100
0	780	700	700	410	400	390
1	720	630	630	400	385	375
2	800	650	600	420	395	375
5	750	550	510	390	395	405
8	850	650	650	410	410	370
12	820	630	570	395	405	365
21	660	580	550	225	420	415

Table 2. CHANGES IN THE TOTAL AND VIABLE COUNTS OF SUSPENSIONS OF *E. coli* STORED AT 22° C. IN THE PRESENCE AND ABSENCE OF CHLORAMPHENICOL

Period of storage (days)	Total count cells per ml. × 10^7			Viable count cells per ml. × 10^7		
	Concn. of chloramphenicol μgm. per ml.			Concn. of chloramphenicol μgm. per ml.		
	0	10	100	0	10	100
0	680	640	660	470	400	430
1	1,050	580	570	530	410	435
2	1,220	660	620	535	425	435
4	960	520	500	220	390	415
7	510	550	520	60	250	350
11	480	350	550	20	60	250

It would seem, therefore, that a bacteriostatic agent such as chloramphenicol need not necessarily increase the tendency of bacteria to die under conditions of bacteriostasis, but may instead help them to survive. Whether death is encouraged or prevented probably depends on the interplay of a number of factors such as species of bacterium, temperature, concentration of chloramphenicol and cell numbers. Differences in these conditions probably explain why Gray[7] and Valentine[8] found that chloramphenicol exerted a bactericidal action on *E. coli.* Work is now proceeding with the view of determining whether, for any given species, at any chosen temperature, there is a critical concentration of chloramphenicol per cell which will retard death.

Evidence for β-Oxidation in the Metabolism of Saturated Aliphatic Hydrocarbons by Soil Species of *Nocardia*

MEMBERS of the genus *Nocardia* can use certain long-chain saturated aliphatic hydrocarbons (C_{10}–C_{18}) as sole carbon and energy source[1], but very little information is available about the mechanism by which these compounds are broken down by micro-organisms[2]. In the present work the breakdown of 1-phenyldodecane, 1-phenyldecane, 1-phenyloctadecane, 3-phenyleicosane and 1-(α-naphthyl)hendecane by *N. opaca* (strain T_{16}) and *Nocardia* spp. (strain P_2) has been shown to give substituted fatty acids. The shorter-chain ethyl, *n*-propyl and *n*-butyl benzenes were not attacked. In the following the methods detailed by Webley, Duff and Farmer[3] were used.

Phenyldecane, phenyldodecane and phenyloctadecane. An experiment with strain T_{16} was set up with about 100 mgm. of 1-phenyldodecane (Eastman Chemicals) in place of the ω-phenyl-substituted fatty acids used previously[3]. Other conditions remained the same except that the phosphate buffer concentration was increased to $0 \cdot 033\ M$. After seven days incubation *o*-hydroxyphenylacetic acid was detected, as formed by strain T_{16} from phenylacetic acid and other ω-phenyl-substituted fatty acids with an odd number of methylene groups[3]. Strain P_2, which does not attack phenylacetic acid, was used in the following experiment. Phenyldodecane (103 mgm.) was added aseptically to 340 mgm. (dry wt.) washed cells (grown for 14 days on glucose (1 per cent (w/v)–nutrient broth at 25°) in phosphate buffer (100 ml.)). The conversion of phenyldodecane to phenyl-substituted fatty acids was estimated by the increase in absorption of acidified 5-ml. aliquots (after removal of cells) at 210 $m\mu$, using phenylacetic acid as a standard. A conversion of 67 per cent was found after 40 hr., increasing to 85 per cent in 6 days. No further change occurred and the experiment was concluded after 12 days. Benzoic acid, if formed, did not exceed 5 per cent of the starting material. Ether extraction of the solution (after removal of cells) gave a solid product the infra-red spectrum of which (after recrystallization) was identical with phenylacetic acid. The R_F value on the paper chromatogram was the same as that of the authentic material.

It was shown similarly that phenylacetic acid was formed from phenyldecane and phenyloctadecane by strain P_2.

3-*Phenyleicosane.* By analogy[3] 3-phenyleicosane was expected to give phenylethylacetic acid, which is not attacked by *N. opaca*. Spectrophotometric analysis showed that after 13 days about 26 per cent of the hydrocarbon appeared as aromatic acids. A fresh batch of washed cells of *N. opaca* was added aseptically to the flask and incubation continued for a further 7 days to give about 56 per cent of the 3-phenyleicosane as aromatic acids. A 5-ml. aliquot examined by paper chromatography showed a spot corresponding to phenylethylacetic acid, but at least two other acids were present.

The remaining contents of the flask were centrifuged, the supernatant sterilized by filtration and a fresh batch of washed cells added. After a further 11 days the cells were removed and the supernatant extracted as before. Paper chromatographic analysis of the oily residue revealed only one spot the R_F of which corresponded to phenylethylacetic acid. The infra-red spectrum also showed that the principal component was phenylethylacetic acid, together with traces of unidentified impurities.

1-(α-*Naphthyl*)*hendecane.* Experiments were performed using both *N. opaca* (T_{16}) and *Nocardia* spp. (P_2) in the manner described for 1-phenyldodecane. After incubation for 10 days (P_2) and 13 days (T_{16}) the ether extracts yielded crystalline products the infra-red spectra of which showed 2-(α-naphthyl)-propionic acid to be the major component and not the expected α-naphthoic acid. Impurity bands showed the presence of some 2-(α-naphthyl)acrylic acid by comparison with a synthetic specimen. Ultra-violet absorption indicated about 17 per cent of this compound. As 2-phenylpropionic acid is rapidly converted by way of cinnamic to benzoic acid[3] by both strains, the failure of the corresponding step with 2-(α-naphthyl)propionic acid may be ascribed to an electronic or steric effect of the larger nucleus.

These results show that $(\omega - 1)$ oxidation[4] is not an important mechanism in the breakdown of substituted long-chain hydrocarbons by these organisms, since this initial step followed by β-oxidation would have led to benzoic acid formation from phenyldecane and phenyldodecane[3]. Initial attack at any of the $(\omega - 2n)$ carbon atoms ($n = 0$, 1, 2 etc.), followed by β-oxidation of the resulting acid, can account for the products obtained, but ω-oxidation ($n = 0$) seems the most probable route.

We are indebted to Dr. J. A. Dixon, of the Pennsylvania State University and the American Petroleum Institute, for specimens of 1-phenyldecane, 3-phenyleicosane and 1-(α-naphthyl)hendecane; to Prof. R. L. Wain, Wye College, for a speciman of 2-(α-naphthyl)-propionic acid; and Dr. Treccani (University of Milan), for the culture of *Nocardia* spp. strain P_2.

Isolation and Characterization of a Naturally Occurring Stimulator of Citrulline Biosynthesis

THE synthesis of citrulline by preparations from mammalian liver requires the addition of ornithine, ammonia, bicarbonate ion, magnesium ion, adenosine triphosphate, and an appropriate derivative of glutamic acid[1]. Synthetic compounds which have been shown to be active in the latter capacity are the N-carbamyl, N-formyl, N-acetyl and N-chloroacetyl derivatives of L-glutamic acid[1]. These compounds have been shown to be catalytically active in the synthesis of carbamyl phosphate, an intermediate precursor of the carbamyl group of citrulline[1-3].

It was desired to ascertain which, if any, of these glutamyl derivatives is the naturally occurring stimulator of citrulline synthesis. Observation of the occurrence of such a stimulator and preliminary progress in the purification of this substance has been previously reported[4]. A concentrated hot-water extract of beef liver, generously provided by the Armour Co., Chicago, was found to contain material which would stimulate citrulline synthesis, and this concentrate proved to be a more convenient starting source for purification than fresh liver. It was further found that Difco Bacto-Yeast Extract (Difco Laboratories, Inc., Detroit, Michigan) and fresh brewer's yeast are potent sources of a similar or identical material. The stimulators from liver and from yeast were purified by chromatography on anion exchange resins and by preparative paper chromatography employing several solvent systems. During purification, the desired material was located and assayed by its ability to stimulate citrulline synthesis in the absence of added glutamyl derivatives.

Both the liver and the yeast stimulator were obtained as crystalline compounds. Both materials moved on chromatograms in a manner identical with authentic N-acetyl glutamic acid. The activity of both stimulators in the citrulline-synthesizing system was virtually identical on a weight basis with that of N-acetyl glutamic acid. Infra-red spectroscopy provided further evidence for their identity.

Acid hydrolysis of both stimulators gave rise to a single ninhydrin-reactive material, which was identified as glutamic acid by paper chromatography in three solvent systems. The yield of glutamic acid from weighed samples of the stimulators was determined by the quantitative ninhydrin method[5]. These yields were in reasonable agreement with the theoretical yield from N-acetyl glutamic acid, the values being 97 per cent of theory in the case of the liver stimulator, and 106 per cent of theory in the case of the yeast stimulator.

It has been reported that N-acetyl glutamic acid is an intermediate in the synthesis of ornithine in *Escherichia coli*[6]. However, this compound has not, to our knowledge, been isolated previously from natural sources. N-acetyl glutamic acid appears to be present in fresh liver in a concentration of about three parts per million, and in Difco Bacto-Yeast Extract to the extent of about 200 parts per million.

Details of the isolation and characterization of these materials will be published elsewhere.

This investigation was supported in part by research grants from the National Institutes of Health and the Wisconsin Alumni Research Foundation.

α-Mannosidase and Other Glycosidases in the Tissues of the Mouse and the Rat, with Special Reference to the Sex Organs

α-Mannosidase, an enzyme previously obtained from sources such as lucerne seed[1], snails[2] and limpets[3], has been found to be widely distributed in the body of the mouse and the rat (Table 1). On the whole, values for infant organs tended to be somewhat higher than the corresponding adult values. The figure for adult mouse uterus was drastically reduced, sometimes to zero, by ovariectomy, and was restored to the normal level by œstrone administration.

Adult epididymis, both caput and cauda, displayed by far the highest α-mannosidase activity observed, in both mice and rats; but the figure for epididymis in immature animals was very much lower, depending on the age. Experiments are in progress to determine whether the high activity in adults is derived from the epididymis itself or from the ripening spermatozoa. It is interesting to note in this connexion that α-mannosidase is strongly inhibited by mannonolactone[3].

Table 1. The α-Mannosidase Activity of Mouse and Rat Tissues

While the possible function of α-mannosidase in the body remains a matter for speculation, mannose is known to occur in several mucoproteins, such as ovomucoid[4] and urinary mucoprotein[5]: the concentration of the latter is higher in male than in female urine[5]. One cannot, however, exclude the possibility that the natural substrate may be quite a small molecule.

The distribution of α-mannosidase in the body and the effect of œstrogen on the uterine level is very reminiscent of β-glucuronidase, an extensively studied mammalian glycosidase[6,7]. Epididymis had not hitherto been studied for β-glucuronidase activity. The figure found was not, however, particularly high in mice and rats, nor did it vary markedly with age. On the other hand the enormous β-glucuronidase activity of female rat preputial-gland[8], which we have confirmed, was not reflected by α-mannosidase.

β-N-Acetylglucosaminidase activity[9] was found to be much higher in adult rat epididymis than in any other tissue examined for this enzyme, but was reduced about 15-fold in infant animals. This enzyme, it should be noted, was shown to be distinct from α-mannosidase: it was not, for example, inhibited by mannonolactone.

Glucuronic acid is present in the acid mucopolysaccharides, hyaluronic acid and chondroitin, while N-acetylglucosamine is present in the former and also in many mucoproteins. There is evidence for the participation of both β-glucuronidase and β-N-acetylglucosaminidase in mucopolysaccharide metabolism[10]. In the case of β-glucuronidase, great emphasis has been placed on its possible role in the metabolism of steroid glucuronides, since the activity of the enzyme in many organs can be altered by sex-hormone administration. It would appear, however, that there are two other glycosidases in animal tissues that may be under the control of sex hormones, and that in common with β-glucuronidase may play some part in mucoid metabolism.

Reversal of Relaxing Mechanism in Muscle Fibre Systems by Hydrostatic Pressure

It is an old observation[1,2] that intact muscle subjected to a hydrostatic pressure of a few thousand pounds per square inch goes into contracture. Further, it was shown by Brown[3] that in the range where contracture is still small, pressure greatly increases the tension of an electrically stimulated twitch, and that this effect occurs if the pressure is maintained only up to the end of the latent period. Thus pressure is promoting a precursor reaction which has been loosely called activation.

The discovery of an *in vitro* contraction cycle by Goodall and A. G. Szent Györgyi[4] provides a model of activation which works simply through small changes of *p*H. It is of interest, therefore, to see how far this system resembles intact muscle in its reaction to pressure.

First the dependence of relaxation on *p*H has to be characterized. It was found by one of us (M. C. G.) that fibres, active not only in the creatine phosphate system but also in the presence of adenosine triphosphate alone, can be obtained if one adds to the 50 per cent glycerol–water extraction fluid 5 m*M* histidine and 2 m*M* sodium cyanide to *p*H 6·8; in which medium they retain their remarkable activity for several weeks. With these the *pK* of equation (2) below is a function:

$$pK = 6{\cdot}45 + 2 \log_{10} [CP]/10 \qquad (1)$$

of the creatine phosphate concentration $[CP]$ (millimolar) provided that the adenosine triphosphate concentration $[ATP]$ is less than $[CP]$, which is the case of physiological interest; and $n = 3$. Similar results hold for adenosine triphosphate alone, for which case the dependence of tension y on *p*H is given in Fig. 1. More complete details will be given elsewhere.

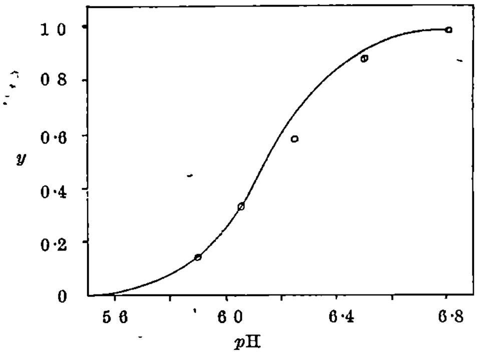

Fig. 1. Dependence of tension (y) on *p*H of extracted muscle fibre (rabbit psoas) in the presence of 10 m*M* adenosine triphosphate, 5 m*M* magnesium chloride and 0·125 sodium succinate buffer. Temperature, 22° C. Curve through points is relation (2) with $P = 0$, $n = 3$, $pK = 6{\cdot}15$

To study the pressure effect a small fibre bundle developing about 1·5 gm. tension was mounted in a pressure bomb designed for rapid access without disturbing the optical recording system. A solution containing the substrates 5 m*M* magnesium chloride and 0·125 *M* sodium succinate buffer to measured *p*H was added. The fibre developed tension and relaxed to a value depending on *p*H. Pressure P was applied in increments of 1,000 lb./sq. in. and the steady state tension y noted. In all cases tension increased reversibly with pressure in accordance with a relation of the form:

$$pY = \log_{10}\left(\frac{y}{1-y}\right) = \frac{P\Delta V}{2{\cdot}3RT} + n(pH - pK) \qquad (2)$$

Fig. 2 shows pY plotted as function of pressure for three typical cases including an intact muscle.

The fact that the slope $\Delta V = 350$ c.c./mol. is the same in all cases confirms the view that the system is a model of intact muscle, since this high value is quite unique for protein transformations[5]. So it is reasonable to use the relation $pH = pK - \frac{1}{n}\, pY(0)$, where $pY(0)$ is obtained by extrapolation to $P = 0$, to estimate the *p*H of intact muscle on the basis of a known intracellular concentration of creatine phosphate. For the slow tonic muscle of Fig. 1, a probable value is $[CP] = 10$ m*M*, giving $pH = 5{\cdot}8$.

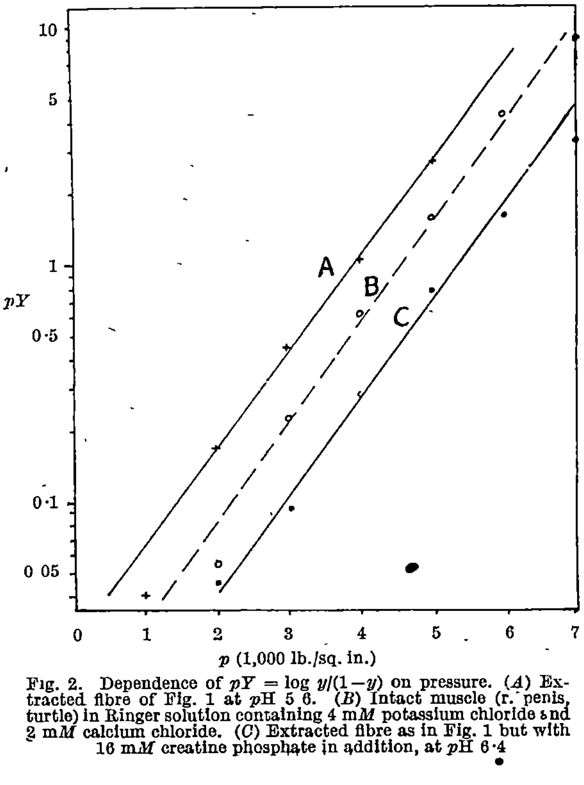

Fig. 2. Dependence of $pY = \log y/(1-y)$ on pressure. (*A*) Extracted fibre of Fig. 1 at *p*H 5·6. (*B*) Intact muscle (r. penis, turtle) in Ringer solution containing 4 m*M* potassium chloride and 2 m*M* calcium chloride. (*C*) Extracted fibre as in Fig. 1 but with 16 m*M* creatine phosphate in addition, at *p*H 6·4

Equation (2) implies that involved with increase of one positive unit charge is a volume increase of $\Delta V/n = 117$ c.c./mol., which is in the normal range for protein transformations[5]. Since volume increase is invariably associated with loss of net charge, we must suppose that the protein is negatively charged. Further, if we accept the view[6] that relaxation is essentially the dissociation of actomyosin (AM) into actin (A) and myosin–adenosine triphosphate complex (M^{nATP}), then the factor 2 in (1) suggests that the overall reaction is something like :

$$AM^{nAMP-} + n\text{H}^+ + 2n \sim P \rightleftharpoons A + M^{nATP} \quad (3)$$

Confirming this view, we found that addition of adenosine monophosphate to 5 mM lowered the pK by 0·5 unit. The function of magnesium, which is essential for this reaction in the concentration used, would be then to inhibit the further splitting of the myosin – adenosine triphosphate complex.

Adequate stirring throughout was necessary to prevent accumulation of products, presumably mainly adenosine monophosphate having the same result as above.

Adaptation of Yeast to Maltose Fermentation

Certain strains of baker's yeast (*Saccharomyces cerevisiae*) have been shown in this laboratory to be capable of fermenting maltose without prior exposure to this sugar provided that the growth conditions are suitably controlled. The fermentation tests were carried out for one hour in the Warburg apparatus under nitrogen, strict precautions being taken to remove all traces of dissolved oxygen from the yeast suspension and substrate solution, and only glucose-free maltose being used, because traces of both oxygen and glucose are known to enable yeast to become adapted rapidly to maltose fermentation[1,2].

This ability to ferment maltose rapidly is a very labile characteristic of the yeast. Early experiments on growing the yeast in the laboratory in a defined medium of glucose or sucrose, salts, vitamins and 'Difco Casamino' acids failed to produce a yeast which on harvesting fermented maltose unless maltose had been included in the growth medium. It was then discovered that a harvest of yeast which would ferment maltose with no appreciable lag at a rate comparable to glucose fermentation could readily be obtained in the absence of maltose in the growth medium, provided that the supply of assimilable nitrogen in the growth medium was restricted. The effect of limited nitrogen could be enhanced by simultaneously restricting the sugar supply (usually glucose).

Table 1

Treatment	Maltose fermentation (μl. CO_2/hr / 10 mgm. yeast)	Yield (mgm. wet weight)
Inoculum	183	(100)
0·014 M amino-N	18	182
0·0036 M amino-N	156	171
0·0011 M amino-N	374	156
0·0004 M amino-N	483	150

Basal medium: 0·425 gm. KCl, 0·246 gm. $CaCl_2.6H_2O$, 0·125 gm. $MgSO_4.7H_2O$, 2·5 mgm. $MnSO_4.4H_2O$, 4·2 mgm. $FeCl_3.6H_2O$, 0·6 gm. KH_2PO_4, 2·5 mgm. pyridoxine, 2·5 mgm. calcium pantothenate, 20 mgm. inositol, to 1 litre with water.

Table 1 contains the results of one of many such experiments, in which inocula of 100 mgm. of yeast (wet weight) were seeded into 200-ml. aliquots of a basal medium as indicated, containing varying amounts of 'Difco Casamino' acids and 0·028 M glucose. After 3 hr. growth at 30° C., with aeration at 500 ml./min., the yeast from each flask was harvested, washed twice with isotonic saline, and samples were immediately examined in the Warburg apparatus.

It will be seen from Table 1 that the decrease in maltose fermentation rate in the 0·014 M amino-nitrogen medium cannot be accounted for by dilution of the intracellular level of existing enzyme by growth; with the two lowest levels of nitrogen there was an overall increase in fermentation activity.

In experiments carried out over 24 hr., yeast of high maltose-fermenting activity was seeded into an aerated synthetic medium containing 0·11 M sucrose and 0·014 M amino-nitrogen (as 'Difco Casamino' acids), with vitamins and salts as before. Aliquots were withdrawn at intervals of 1 hr. and the yeast was spun down, washed and tested immediately in the Warburg for maltose fermentation.

The yeast sample withdrawn after the first hour had one-third of the maltose fermentation rate of the original seed, the latter evolved 272 µl. carbon dioxide/hr./10 mgm. yeast (wet weight), whereas the sample withdrawn at one hour evolved 76 µl. By the third hour the rate had fallen to zero and there was no activity until the ninth hour, when a low rate of 21 µl. was recorded. The rate then steadily increased until by the twenty-fourth hour of growth the activity was 283 µl. The loss of ability to ferment maltose when seeded into a fresh medium containing ample nitrogen is quite reproducible, as is the induction of the maltose-fermenting system in media containing little nitrogen and sugar. Similar results were obtained using media where the sole nitrogen source was DL-asparagine or ammonium sulphate; but the degree of response was always less than for casein hydrolysate.

Moreover, if the rate of growth was restricted by other means, for example, by supplying galactose as sole sugar, or omitting vitamins, or severely reducing the glucose level in the medium, then even in the presence of excess nitrogen maltase synthesis was induced. Table 2 contains results of one such experiment. It has not yet been determined whether the effect is due to the overall diminished growth activity, or to a restriction of nitrogen uptake per cell arising from this diminished activity, although determination of the nitrogen content of harvested yeast cells by a modification of Conway's procedure[3] shows only a weak inverse correlation between maltose fermentation and nitrogen, with a much stronger

Table 2

Treatment	Maltose fermentation (μl. CO_2/hr./ 10 mgm. yeast)	Yield (mgm. wet weight)
Inoculum	109	(100)
0·014 *M* amino-N, 0·056 *M* glucose	31	197
0·014 *M* amino-N, 0·056 *M* galactose	747	140
0·014 *M* amino-N, 0·0056 *M* glucose	658	169
0·014 *M* amino-N, 0·056 *M* glucose, omitting vitamins	556	193

inverse correlation between yield and fermentation rate.

The maltose-fermenting system of these yeasts must be considered as adaptive owing to its extreme lability. Yet such activity can be induced in the absence of maltose or a substrate analogue by altering the cultural conditions in one of several ways to restrict growth. In view of the current interest in enzyme adaptation it is obviously of importance to ascertain whether other of the known adaptive enzyme systems will respond in this way. Recently, White[4] has described experiments on yeast from which he concluded that ability to ferment maltose, and glucose, often proved to be a function of the stage of the harvesting of the yeast crop. The likelihood is that the variations found were a function of the concentration of sugar or nitrogen in the medium at the time of harvest.

It is hoped to publish a full account of this work with experimental details elsewhere.

We would like to thank our colleagues in this Department for their help and criticism, and also the Directors of the Distillers Company, Limited, for permission to publish this work.

A Factor influencing the Protozoal Population in Sheep

THE quantitative importance of the protozoa in ruminal digestion has not yet been positively assessed. The recent work of Sugden and Oxford[1] and Sugden[2] shows unequivocally that various protozoa digest both starch and cellulose and also utilize a number of soluble carbohydrates[3]. Furthermore, McNaught *et al.*[4], using rats, showed that the protozoa yield a protein of higher biological value than the ruminal bacteria.

The concentration of the ruminal protozoa is strongly influenced by diet[5], but from the results of a number of experiments in this laboratory, it became apparent that the composition of the diet may be overshadowed by other factors. One such factor has been observed in an experiment designed to determine the influence, on ruminal metabolism, of feeding, in five different ways, a simple ration of roughage and sheep cubes to Merino sheep. The 700-gm. daily ration was palatable and eaten avidly as soon as presented. The five treatments were used in a 5 × 5 Latin square design. These, together with the mean protozoal counts, are shown in Table 1.

Table 1

Ration No.	Treatment	Protozoa × 10^6/ml. (Mean of 5 sheep)	
4	$\frac{1}{4}$ ration fed at 09.00, 11.00, 13.00 and 15.00 hr.	3·14	
3	$\frac{1}{2}$ ration fed at 09.00 and 17.00 hr.	2·26	2·29
1	Roughages fed at 09.00 hr., sheep cubes at 17.00 hr.	2·34	
5	Sheep cubes fed at 09.00 hr., roughages at 17.00 hr.	2·26	
2	Whole ration fed at 09.00 hr.	1·15	

L.S.D. 5% = 0·666
1% = 0·93
0·1% = 1·32

Rumen samples were taken by stomach tube on the final day of each 4-week period, immediately before feeding. Counts were made by a modification of the method outlined by Adam[6].

A sharp division of the protozoal counts into three levels is apparent, notwithstanding the fact that the same diet was used throughout. Treatment 4 is significantly higher than all other treatments ($P < 5$ per cent). No significant difference exists between treatments 3, 1 and 5, but these are all higher than treatment 2 ($P < 1$ per cent).

The relationship of these data to ruminal conditions awaits assessment, but they show clearly that the eating habit of the animal can be an important factor in determining the level of the protozoal population.

Use of the Cervical Mucus Smear in assessing Ovarian Activity in the Ewe

PAPANICOLAOU[1,2] noted that when the cervical mucus of women was spread to dry on a glass slide a characteristic "crystallization" took place. This phenomenon has been investigated by Zondek[3]. Its use as a simple test for determining ovarian function has been extended recently to domestic animals, notably the cow[4-8]. So far we are not aware of any such studies with the ewe.

The complexity of the external orifice of the cervix, particularly in aged ewes, presents a difficulty in the collection of a cervical specimen uncontaminated with vaginal mucus. With experience mucus was readily obtained through use of a 'Coldite' vaginal speculum and glass rod, or directly from slaughtered animals. Smears on a clean glass slide were examined microscopically under low power when dry. It was found necessary to warm slides before examination in cold weather. The fern-like patterns disappeared fairly rapidly on cooling again. Cervical mucus was recovered from Romney ewes running with raddled

Table 1. "CRYSTALLIZATION" IN CERVICAL MUCUS SMEAR DURING THE ŒSTROUS CYCLE OF THE EWE

Day of cycle	−7	−6	−5	−4	−3	−2	−1	0	+1	+2	+3	+4	+5	+6
No. showing positive	0	3	4	6	12	18	25	33	21	6	0	2	0	0
Total smears	9	13	15	25	27	28	27	33	33	30	19	9	5	2
Per cent showing positive	0	23	27	24	44	64	93	100	64	20	0	22	0	0

teasers during anœstrus and the breeding season. Mucous secretions of the cervix from pregnant ewes and from castrated and hysterectomized animals were observed, as well as cervical mucus from ewes receiving injections of œstrogens, progesterone and the gonadotrophin from pregnant mare serum.

During the œstrous cycle the fern-like patterns were present in association with œstrus as shown in Table 1. No such "crystallization" occurred in specimens taken in late pregnancy, in anœstrus or from uninjected ovariectomized ewes. Toward the end of the breeding season when the phenomenon of 'silent œstrus' is not uncommon the cervical mucus suggested ovulation unaccompanied by œstrus in several ewes. Ovulation in some instances was confirmed by recovering the ova a few days later. Likewise, patterns were seen when ovulation was induced with pregnant mare serum in five anœstrous ewes. Three hysterectomized ewes were available for study. Negative mucus persisted for several months during the breeding season, indicating perhaps that the life of the corpus luteum had been prolonged[9]. While none of these ewes has been in œstrus since, it is interesting to note that the negative mucus was superseded by fern-like patterns before the end of the breeding season and these positive smears have continued. The ovaries of one animal are being examined histologically.

In thirty-seven œstrous cycles a single injection of œstradiol benzoate was given to study the inhibiting effect of progesterone on pattern formation during the luteal phase. On the third day post-œstrus both 100 μgm. and 50 μgm. œstradiol benzoate induced a positive mucous smear. These same levels of œstrogen on the sixth day resulted in one positive response only in four animals treated at each level. Administration of $\geqslant$ 150 μgm. was completely successful. From the ninth to twelfth day $\geqslant$ 50 μgm. always caused pattern formation, as did several injections of 20 μgm. This greater sensitivity in the late luteal phase may reflect a reduced inhibitory effect, lower progesterone secretion or an increase in endogenous œstrogens.

Another phase of the work, using ovariectomized ewes, was to study the quantitative relationship of progesterone to œstrogens when the hormones were injected simultaneously. It is known that progesterone pretreatment in the ewe results in a marked increase of sensitivity to œstrogen[10]. When 10 mgm. progesterone was administered daily for three days prior to the simultaneous injection of œstrogen and 10 mgm. progesterone we noted that 20–25 μgm. œstradiol benzoate caused "crystallization" and $\geqslant$ 50 μgm. led to œstrous behaviour. The marginal levels when œstrogen was given as a single injection 40 hr. after the progesterone priming were 15 μgm. and 25 μgm. respectively.

These results show a high degree of sensitivity on the part of the cervical mucus smear to œstrogen and progesterone, and therefore suggest its suitability in determining the quantitative production of the ovarian hormones in the ewe.

One of us (M. F. M.) is indebted to the New Zealand Wool Board for a scholarship.

Manganese Deficiency in *Chlorella* under Heterotrophic Carbon Nutrition

IN the course of an investigation of the effect of manganese on nitrogen metabolism in *Chlorella*, limitations in growth of *Chlorella* due to lack of manganese have been obtained under autotrophic, mixotrophic and heterotrophic conditions of carbon nutrition with both nitrate and ammonium as nitrogen sources. In the recent report of Pirson and Bergmann[1], it is stated that for *Chlorella vulgaris*, "manganese deficiency has no influence upon growth in heterotrophic culture in darkness".

Chlorella vulgaris var. *viridis* has been grown in a solution of purified nutrients in an apparatus[2] devised for the rapid growth of *Chlorella* under normal and micronutrient deficient conditions. No measurable growth took place in the purified nutrient solution without the addition of manganese. In this study, normal culture solutions were supplied with 0·4 p.p.m. of manganese, and deficient solutions, except autotrophic cultures, were supplemented with 0·004 p.p.m. of manganese. The nitrate autotrophic culture received 0·003 p.p.m. of manganese and the ammonium autotrophic culture, 0·008 p.p.m. of manganese. Glucose, purified by passage through a mixture of 'Dowex 50' and 'Dowex I', was included in mixotrophic and heterotrophic cultures at a concentration of 1 per cent.

Growth of *Chlorella* (Table 1) was limited when manganese was deficient under all conditions of carbon nutrition. This is in contrast with the experience of Pirson and Bergmann[1]. Manganese, as a contaminant in their nutrient solutions, may account for the failure of these workers to obtain manganese-deficient effects under heterotrophic conditions.

Table 1. TERMINAL GROWTH OF *Chlorella* UNDER VARIOUS CONDITIONS

Carbon nutrition	Packed cell volume ml /l.		Dry weight mgm /ml.	
	Mn-sufficient	Mn-deficient	Mn-sufficient	Mn-deficient
	Nitrate as nitrogen source			
Autotrophic	11	4	3·2	1·4
Mixotrophic	13	6	3·5	2·2
Heterotrophic	23	14	5·5	7·3
	Ammonium as nitrogen source			
Autotrophic	8	4	3·0	1·5
Mixotrophic	11	5	3·5	1·9
Heterotrophic	16	12	5·0	3·8

Table 2: THE MANGANESE STATUS OF *Chlorella* CELLS GROWN IN THE PRESENCE OF LOW LEVELS OF MANGANESE

Carbon nutrition	Nitrogen source	Growth per added Mn μl./μgm.	Manganese content		Manganese* recovered in cells per cent
			Packed cell volume basis μgm./ml.	Dry wt. basis μgm./gm.	
Autotrophic	Nitrate	1,300	2·0	5·6	114
Mixotrophic	,,	1,600	0·6	1·7	46
Heterotrophic	,,	3,500	0·4	1·3	64
Autotrophic	Ammonium	475	2·0	4·8	63
Mixotrophic	,,	725	0·2	0·6	14
Heterotrophic	,,	3,000	0·3	1·0	45

* Manganese content of nutrition solution was found to be 0·003 p.p.m.

These results show that for the same amount of manganese, growth under heterotrophic conditions was greater than in the light. This is in accord with the observations of Pirson and Bergmann[1]. The point is more clearly demonstrated when the growth data were calculated as microlitres of *Chlorella* produced per microgram of added manganese (Table 2). However, when the manganese content of the cells was determined[3], the striking difference was shown to be between the presence and absence of added glucose, and not between light and dark.

If manganese requirement is based on its level in the manganese-limited cell when growth ceases, such a requirement is clearly several times higher for photosynthesis than for other functions.

The quantity of manganese recovered in the cells (Table 2) suggests an explanation for the apparent difference in manganese requirement based on growth response as compared with manganese content. Thus, the recovery of manganese was less under mixotrophic conditions than under autotrophic or heterotrophic conditions, indicating that in the presence of both photosynthesis and glucose metabolism, manganese absorption was impaired. Unfortunately, it was impossible to confirm this further by analysis of the residual solution.

Since manganese is involved in so many enzymatic processes[4] it is not surprising to find that it is required under heterotrophic conditions. However, it is clear that most of the requirements under autotrophic conditions are for photosynthesis. The requirement of manganese for photosynthesis has been shown[5] previously. It is now suggested that the apparently high requirement of *Chlorella* for manganese under mixotrophic conditions is due to restricted manganese absorption and that the low requirement for manganese under heterotrophic conditions has obscured the actual need for this element.

Note added in proof. Eyster, Brown and Tanner (*Arch. Biochem. Biophys.*, **64**, 240 (1956)) have reported that there is no Hill reaction in manganese-deficient *Chlorella* cells and that photosynthesis is 25 per cent of normal.

A Phosphate Requirement for Nitrate Reductase from *Neurospora crassa*

THE enzyme nitrate reductase which catalyses the reduction of nitrate to nitrite in some bacteria[1], fungi[2–4] and green plants[5] has been shown to be a flavoprotein[6] containing molybdenum[2–4]. During enzyme action the micronutrient undergoes a valence change[7] involving Mo^{6+} and Mo^{5+}.

This communication reports that further purification of nitrate reductase from *N. crassa* has shown it to have a requirement for phosphate which can be replaced completely by arsenate, tellurate or selenate and partially so by silicate or sulphate.

N. crassa wild type 146 (microconidial type) was grown in a modified Fries medium containing ammonium nitrate as the source of nitrogen[2]. The media were dispensed in 200 ml. amounts in 1-litre Erlenmeyer flasks sterilized for 10 min. at 10 lb. per sq. in., cooled and inoculated with a spore suspension of the fungus. After four days growth at 28° C. in the dark, the felts, harvested in a Büchner funnel, were well washed with distilled water and frozen for 3 hr. at – 15° C. They were ground in a pestle and mortar with three times their weight of cold 0·1 *M* phosphate buffer (*p*H 7·5) and then in a Ten Broeck glass macerater. The homogenates were centrifuged at 3,000*g* for 15 min. at 0° C. The supernatant was fractionated with ammonium sulphate, calcium phosphate gel and carbon adsorption procedures as summarized in Table 1.

The final enzyme preparation was dissolved in distilled water and represented an 84-fold purification of the enzyme. Protein was determined by the Folin method[8].

The enzyme was assayed as follows: 0·1 ml. enzyme (100 μgm. protein/ml.); 0·1 ml. 0·1 *M* potassium nitrate; 0·02 ml. boiled, *tris*(hydroxymethyl)amino-methane extract of acetone powder of pig heart (*p*H 7·5); 0·05 ml. 2 × 10^{-3} *M* reduced triphosphopyridine nucleotide and 0·1 *M* *tris* buffer (*p*H 7·5) to a final volume 0·5 ml. In the control tubes reduced triphosphopyridine nucleotide was omitted. After 10 min. incubation at 25° C., nitrite

Table 2. THE SUBSTITUTION OF OTHER ANIONS FOR PHOSPHATE IN NITRATE REDUCTASE (FRACTION VI)
(Values as per cent)

Anions	PO_4'''	P_2O_7''''	ATP	AsO_4'''	BO_2'''	SiO_3''	VO_3'	MoO_4''	MoO_3''	WO_4''	SO_4''	SeO_4''	TeO_4''
Exp. 1	100	0	0	97	0	48	0	0	0	0	42	100	100
,, 2	100	0	0	120	0		0	0	0	0	91	100	100
,, 3	100	0	0	62	0	35				0	62	100	100
Mean	100	0	0	93	0	42	0	0	0	0	65	100	100

Anions dispensed in 0·05 *M tris* buffer (*p*H 7·5). Enzyme assay as in text; plus anion in 0·1 ml. at a final concentration of 10^{-2} *M*.

was determined by adding sulphanilamide and N-(1-naphthyl)-ethylenediamine reagents[7].

Reduced triphosphopyridine nucleotide was prepared by reducing triphosphopyridine nucleotide with isocitric dehydrogenase extracted in 0·1 *M tris* buffer (*p*H 7·5), from acetone powder of pig heart.

The effect of adding graded amounts of phosphate *in vitro* to 0·1 ml. of the purified enzyme (fraction VI) containing 110 μgm. protein/ml. is shown in Fig. 1. Maximal activity was obtained when 2·5 μ*M* phosphate was added to 0·1 ml. of the enzyme. Adenosine triphosphate at either 10^{-2} or 10^{-3} *M* did not substitute for inorganic phosphate. The enzyme was not inhibited by uncoupling reagents, for example, dinitrophenol at 1×10^{-5} and 10^{-4} *M*; aureomycin at 5×10^{-4} *M* or sodium arsenite at 1×10^{-2} *M*, so that there is no evidence, in these experiments, for a phosphorylation mechanism during nitrate reductase action.

The results in Table 2 show that the phosphate requirement can be replaced completely by selenate, tellurate or arsenate and to a lesser extent by sulphate or silicate, each at a final concentration of 10^{-2} *M*.

It is likely, therefore, that one of the roles of phosphate in nitrate reductase is to bind the molybdate to the apoenzyme, as the replacement anions which have similar atomic radii to phosphate (2·76 A.), being within the range 2·4–2·8 A., also form complexes with molybdates.

A full account of this and related work will appear elsewhere.

Thiamine-deficiency of *Prototheca*, a Yeast-like Achloric Alga

IN 1894, Krüger[1] described two micro-organisms isolated in Germany from mucous flux of *Tilia* and *Ulmus* spp., namely, *Prototheca moriformis* and *P. zopfii*. Although the generic diagnosis indicated the micro-organisms to be fungi, they could not be connected with the Saccharomycetes nor with the lower Phycomycetes. Chodat[2] showed that the genus should be referred to the achloric strains of the alga *Chlorella*; this was confirmed later on by Printz[3]. Ashford *et al.*[4], isolating *P. portoricensis* and its variety *trispora* from cases of human sprue in tropical areas, confirmed the ability of this genus to grow also on chemically defined media, although best growth was always obtained in peptone-containing media. Negroni and Blaisten[5] reported that it was impossible to cultivate *P. ciferrii*, isolated from potato skin, in the absence of peptone. More recently, Butler[6] induced by radiation a number of chlorophyll-less mutants of *Chlorella pyrenoidosa* that, in his opinion, could be referred to the genus *Prototheca*. The achloric strains can grow on chemically defined media and do not require vitamins or other growth factors.

Investigations under way in this Institute showed that, in the presence of peptone as nitrogen source, four species of *Prototheca* (*P. zopfii*, *P. portoricensis*, *P. port.* var. *trispora* and *P. ciferrii*), grew well utilizing a wide variety of carbon substrates. On the contrary, all the species failed to grow in media containing glucose, inorganic salts and amino-acids. The vitamin requirements of *P. portoricensis* var. *trispora* are shown in Table 1.

The results were confirmed when thiamine or peptone or their mixture were added to a chemically defined vitamin-free medium (Table 2).

A more extended investigation, including Butler's achloric strains of *Chlorella pyrenoidosa*, is now being made; it will be reported in detail elsewhere. But it may be concluded that some nutritional requirements of *Prototheca* and *Prototheca*-like *Chlorella* strains are quite different. The absence of vitamin-deficiencies of the achloric mutants of *Chlorella* indicates a metabolism still autotrophic while natural

Thorium-bearing Minerals in New Zealand

In the course of a comprehensive study of the opaque mineral sands of New Zealand, the occurrence of thorium-containing minerals of medium density has been noted in the Westport area. Dr. C. O. Hutton, of Stanford University, California, has identified the principal minerals responsible as thorium-bearing sphene and the epidote allanite (private communication).

That part of a fairly crude magnetically separated fraction that sank in bromoform, s.g. 2·8, but which floated in methylene iodide, s.g. 3·3, analysed 0·1 per cent thorium oxide by chemical methods. (Analysis of the thorium oxide was carried out by the Dominion Laboratory.) The ratio of the weight of this fraction in the sample studied to the weight of ilmenite contained was approximately 1 : 7.

D. S. Nicholson[1] has roughly estimated that from surface indications there could be some 90 million tons of sand containing some 5 million tons of ilmenite in the area. It is assumed, but has not been established, that the thorium-containing minerals occur throughout the deposits.

It is understood that neither mineral is a commercially acceptable source of thorium to-day.

A Through-conducting System co-ordinating the Protective Retraction of *Alcyonium* (Coelenterata)

Although Milne-Edwards[1] and Hickson[2] report the existence of co-ordination between the polyps of *Alcyonium*, there is very little to be found in the literature beyond this bare record. Kassianov[3] comes to the conclusion that there is no colonial nervous system in *Alcyonium*. Kukenthal[4] states that in Alcyonaria the existence of a colonial nervous system must be inferred from (presumably mechanical) stimulation experiments. On the other hand, Hyman[5] concludes that "in most Alcyonarians a nervous plexus seems to be absent from the wall of the anthocodia and the general coenenchyme", except that "the occurrence of such a plexus in the coenenchymal epidermis has been verified for *Veretillum* and may be expected in many Pennatulacea".

The use of electrical stimulation has recently revealed a through-conducting system which co-ordinates the protective retraction of polyps in several groups of Octocorallia. In *Alcyonium*, *Solenopodium*, *Tubipora* and some colonies of *Heteroxenia*, a single electrical stimulus produces no contraction of the polyp columns, though tentacles anywhere on the colony may respond with a jerk. A second stimulus applied anywhere relative to the first initiates a wave of contraction of the tentacles and columns of all the polyps of the colony. This experiment shows that the first stimulus produces a state of excitation over the whole colony, though without a visible reaction. By progressively shortening the interval between the two shocks until the second produces no effect, the refractory period of the through-conducting system has been measured in some instances. For the following Red Sea species at 25°–26° C. the refractory periods were: *Heteroxenia*[6], 0·08 sec.; *Tubipora*[7], 0·02 sec.; *Solenopodium*[8], 0·05–0·1 sec. In the cold-water species *Alcyonium digitatum* it was 0·15–0·2 sec. at 16°–17° C.

However, there could be a localized effect of successive stimuli in addition to the above straightforward through-conduction. To test this possibility in *Alcyonium*, a comparison has been made between the contraction of the polyps in response to eight shocks at 1-sec. intervals applied to the same point, and eight shocks at 1-sec. intervals applied to widely separated points. Eight shocks are a convenient number because they produce a large but incomplete retraction. A difference in degree of contraction over the colony would have implied a summation at the one point, but in fact no difference has been found in twenty-five to thirty small colonies tested. The same experiment carried out on *Sarcophytum* has quite a different result. Summation of several electrical stimuli at one point is there essential before through-conduction is initiated[7]. In large colonies of *Alcyonium* (greater than 15 cm. long) through-conduction may not be complete, because it has been noted that even in small colonies through-conduction sometimes fails between lobes.

The histological basis of the through-conducting system of *Alcyonium* has not been identified directly. An old controversy concerning the existence of nerve cells in the mesoglœa appears to have been settled by Kassianov[3], who describes a nerve net only in the walls of the endodermal tubules, not in the mesoglœa or the ectoderm of the syndete. There is no indication that this histological endodermal net entirely corresponds with the physiologically observed through-conducting system. The ectodermal muscle sheets and associated nerve nets, which are well developed in the individual polyps, apparently have no connexions between polyps[3]. This agrees with the sharp localization of the feeding responses of individual polyps, which can be referred mainly to the ectodermal musculature. When a very small electrode, carrying condenser shocks at 5/sec., is brought up to a polyp disk or tentacle, a feeding reaction or a slow retraction can be elicited from this one polyp alone; but if the through-conducting system is excited, then distant polyps retract no less than neighbouring ones.

Arterio-Venous Anastomoses in the Teat of a Cow

RECENT studies of the circulation in the skin of cattle have shown that arterio-venous anastomoses occur in the ear of the calf and also in the skin of the forehead and cheek[1,2] but not in the skin of the general body surface[2]. Since they might possibly occur in the skin of other extremities the following investigation was carried out.

At autopsy the tip of a teat of an Ayrshire cow and pieces of skin from the end of the tail and from immediately above the hoof of an Ayrshire calf were obtained. They were fixed in 5 per cent formol-saline and embedded in paraffin. Serial sections of the blocks were cut and stained by Masson's trichrome method.

On examination of the sections no arterio-venous anastomoses were found in the skin of the tail and the leg. They were present, however, in the teat, where they could be recognized by the epithelioid cells in their media. In the serial sections it was possible to trace their course from artery to vein. All were apparently in the contracted state. Their outer diameters ranged from 60 to 150µ. Some were short and unbranched while others were tortuous and branched. A typical arterio-venous anastomosis is shown in Fig. 1. It has been sectioned at a bend in its course, as can be seen from the shape of its lumen.

The presence of arterio-venous anastomoses in the teats of any species has not been previously reported. It is possible[3,4] that they may help to control local temperature in conditions of extreme heat and cold. However, they may also be associated with the mechanism of erection of the teat. Although it has been found[5] that the most essential factor in the erection of the human nipple is the contraction of the smooth muscle core, yet some vascular engorgement of the small sinus-like vessels in the dermal papillæ may also occur. Similar sinus-like vessels occur in the dermal papillæ of the cow's teat. It seems possible that the arterio-venous anastomoses may control the flow of blood through these sinuses just as the arterio-venous anastomoses in the tongue of the dog, the sheep and the goat may control the flow of blood through the capillaries of the papillæ[6,7].

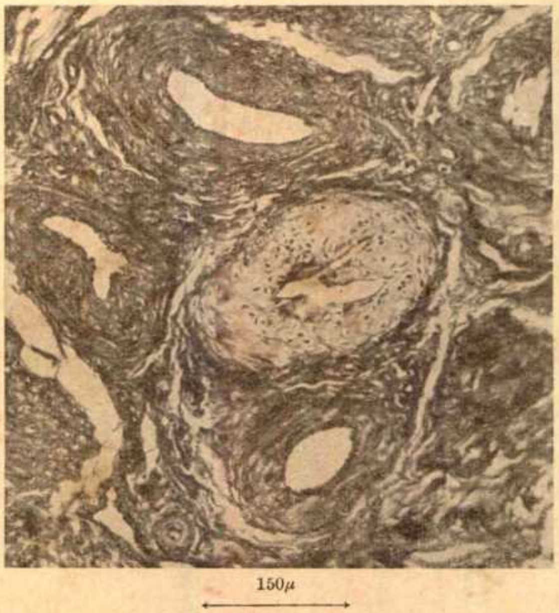

Fig. 1. An arterio-venous anastomosis cut obliquely at a bend in its course. Note the epithelioid cells in its thick wall. Beneath it lies the artery from which it arises, while above it and to the left lie the veins into which it drains

It is proposed to examine the human nipple and the teats of other animals to find if the occurrence of arterio-venous anastomoses in this location is common in mammalia. Examination of latex casts of the blood vessels of the teat may indicate whether the arterio-venous anastomoses control the blood supply to the sinus-like vessels in the dermal papillæ.

Root Dissection: a Method of studying the Distribution of Active Mycelia within Root Tissue

THE presence of saprophytic micro-fungi in the decomposing cortex of roots of rye-grass[1] has been studied by a simple modification of a technique, described by Harley and Waid[2], which was developed to study the active mycelia of root surfaces. Roots at various stages of decomposition, characterized by the colour and condition of the cortex, were selected from rye-grass (*Lolium perenne* L.) growing under field conditions. The roots were washed by agitation in ten changes of 10 ml. of sterile water, and were then cut into 2-mm. fragments from which the outer cortex was dissected, leaving the central cylinder comprising the inner cortex and stele. Dissection was carried out in dishes of sterile water using sterile forceps and scalpel; with practice this could be done by eye. The 2-mm. fragments of outer and inner

† 3–5 cell layers, 39–97μ thick, forming about 35 per cent of the total dry wt. of an intact root.
‡ 2–4 cell layers, 19–68μ thick.
§ 184–232μ in diameter.
‖ Percentage of root fragments inhabited by these fungi in samples of 386 root-surface, 393 outer-cortex and 543 inner-cortex fragments.

cortex and of intact roots were placed on three separate series of plates of Czapek–Dox agar and incubated for a period of three weeks at 25° C. The results, summarized in Table 1, demonstrate the differences which occurred between the composition of the mycelial populations of the root surfaces of intact roots and those of the outer and inner tissues of the cortex of dissected roots. Some of the sterile species of fungi isolated from the inner cortex were rarely isolated from intact roots, presumably because they could not compete in mixed culture with such surface-inhabiting species as *Trichoderma viride* or *Mucor* spp.

The technique can be used to determine the spatial relationships of different fungal species within plant tissue. An interesting example is the distribution of the mycelium of *Fusarium culmorum* in decomposing roots of rye-grass. In samples of 486 fragments, this fungus occurred in 135 outer and 24 inner cortex fragments. Generally, several consecutive fragments of outer cortex were infected with *F. culmorum*. Eighteen of the records from the inner cortex occurred on fragments which had been surrounded by an outer cortex that was infected with *F. culmorum*. Three of the remaining six records from the inner cortex were located in fragments which were adjacent to regions of infected outer cortex. The observations indicate that the ability of *F. culmorum* to infect the inner cortex was dependent upon its initial establishment in the outer cortex. This is in contrast to the distribution of some of the more abundant species of sterile fungi from the inner cortex which were isolated infrequently from the outer cortex (Table 1). I suggest that similar techniques might be developed to follow the course of infection by pathogenic fungi in diseased plant structures.

Attempts have been made to isolate the mycorrhizal fungi associated with beech (*Fagus sylvatica* L.). Microscopic inspection showed that the outer layers of the hyphal mantle which encloses the cortex of infected roots of beech consisted of the hyphæ of several species of fungi, some of which were non-septate and some septate with dark-coloured hyphal walls. This meant that the isolation of the ectotroph would be subject to contamination by the non-mycorrhizal fungi which inhabit the mantle surfaces. To avoid such contamination the mycorrhizal roots were washed in sterile water and the mycorrhizal mantle was then removed by dissection. Several kinds of sterile mycelium were isolated from the root cortex in various types of culture media, and it is possible that they had occupied the intercellular spaces of the outer cortex, that is, the region of the Hartig net. Fungi isolated from the hyphal mantle were mainly sporing forms.

I wish to thank Dr. J. L. Harley and the Director of the Grassland Research Institute, Dr. William Davies, as well as Mr. T. E. Williams, for their encouragement, also the Agricultural Research Council for a training grant during the tenure of which the studies on beech were made.

Some New Observations on the Development of the *Proteus* Group of *Amoebae*

FOR no member of the *proteus* group of *Amoebae* is there any published account of what takes place between the hatching of the spore and the attainment of adult size. (Throughout this communication Jepps[1] has been followed in the use of the terms spore, cyst and *proteus* group.) The technique[2] of removing mature *Amoebae* from their culture to a dilute inorganic fluid (KCl, 0·006 gm.; $MgSO_4.8H_2O$, 0·002 gm.; $CaHPO_4$, 0·004 gm.; 1,000 ml. Glasgow tap water), thereby changing the *p*H of their environment, has facilitated the elucidation of these stages and therefore of giving some explanation of why 4–6 months are occupied by the juvenile stages. When adult they divide by fission once in three days—a striking contrast.

All mature *Amoebae* of this group contain some spores. For the sake of simplicity the species *A. lescherae* will be used to portray the new knowledge acquired. It is needless to emphasize the precaution of dealing with a culture of *A. lescherae* uncontaminated with any other amoeba species.

Introduce into a Petri dish (4 in. diam.) half-filled with inorganic fluid about 20 mature *A. lescherae*. The *Amoebae* are killed, spores released and bacterial decomposition sets in. After about a week (60° F.) hatching amoebulae, 5–6μ, may be studied with a 4·4-mm. water immersion lens *in situ*. These feed and then encyst (? digestive cysts). After a varying period of time, not less than a week, excystation takes place. It is a beautiful sight to see the creatures emerging through a minute opening and freeing themselves from the cyst wall. When half-way through, they look like balloons tied round the middle. These creatures feed, and their growth is accelerated if minute flagellates are added. Once more, these now larger amoebulae encyst. Encysted amoebulae can always be distinguished from spores by their possession of food vacuoles.

After a varying period of time, even so long as a month, excystation again takes place. So the story goes on: a feeding stage, followed by encystment, excystation feeding and consequent growth. The largest cysts after three months measure 39μ. The *Amoebae* emerging from these large cysts grow rapidly to adult proportions, but they are almost transparent.

Thus during the juvenile stage a much longer time is spent in cysts than in active stages. What induces excystation, an excystment factor[3] or a favourable environment, has still to be investigated. A fuller account of this work will be published elsewhere.

Tagging Green Turtles, 1951–56

ON three little islands off the south-west coast of Borneo, the Sarawak Turtle Board annually collects for sale or replants for hatching more than a million eggs of the green or edible turtle (*Chelonia mydas* Linn.)[1]. In 1951 we commenced marking experiments on this population. By 1953 we had settled on polished, monometal, hard-steel, 'cow-ear' type tags—one side with an inset code-number; "SARAWAK MUSEUM: REWARD" on the other. These are punched and locked through the inner rear trailing edge of one forward flipper on an adequate sample of laying turtles.

First 1953 returns showed repeated laying in following weeks of the 'season'[2]. But no 1953 turtle repeated in 1954; and so through 1954–55, until 1956 (about 4,000 tagged). It is unlikely that tags could be regularly overlooked at these three small beaches, where every female is numbered in, flagged, clocked and the clutch-size recorded on an all-night rota, by trained Malay watchers.

The first proved 'over-season' repeat came on July 4, 1956, from a turtle initially tagged on July 30, 1953. By the end of July, fourteen had been recorded, *all* tagged in July or early August 1953. This trend has continued increasingly to date. Many of the 1953+56 recoveries have repeated several times in the latter year, as in the former: *B* 1544 has now laid well over 1,000 eggs on eleven recorded visits, five in 1953 and six in 1956.

The immediate result is a proved method of tagging sea-turtles, durably and harmlessly. Only one number has been eroded. No turtle has been visibly injured. Previous attempts, notably by Schmidt[3] and Moorehouse[4], only succeeded over short periods. Prof. A. Carr is now using these tags on Atlantic green turtles; he already reports significant results[5]. I shall be pleased to correspond with others interested.

A Selective Medium for the Isolation of Coliform Soft Rot Bacteria from Plant Tissue

DURING further studies on black leg disease of potato, difficulty was experienced in isolating the appropriate pathogens, which were identified as *Erwinia atroseptica* (van Hall) Jennison syn. *Bacterium atrosepticum* (van Hall) Burgwitz. Even using the screening methods of Noble and Marshall[1], namely, seeding plates of meat infusion agar with contaminated material from infected stems and tubers, selection of the organisms was difficult owing to the growth of many other types of bacteria. MacConkey's lactose bile-salt neutral red agar was found to be more selective, but *Pseudomonas* spp. could not now be identified by fluorescence in ultra-violet light, although a number still grew on the plates. The selective pectate gels of Rudd-Jones[2] and others were also tried, but proved to be difficult to prepare especially with limited facilities, and were often too soft to use for plating.

One of the characters of the coliform soft rot bacteria is their ability to grow and produce an acid reaction in salicin basal-salt media. A solid medium was therefore devised which would be selective and would allow this reaction to take place as an aid to identification.

The constituents are as follows:

Salicin	10·0 gm.
Sodium taurocholate	5·0 ,,
Ammonium dihydrogen phosphate	1·0 ,,
Magnesium sulphate ($MgSO_4 7H_2O$)	0·2 ,,
Potassium chloride	0·2 ,,
Bromthymol blue (water soluble)	0·05 ,,
Agar	20·0 ,,
Distilled water	1 litre

The ingredients are mixed in a flask and dissolved by steaming. The *p*H is corrected to 7·0, the medium tubed and sterilized by bringing the pressure in the autoclave to 15 lb. momentarily, then switching off. In preliminary experiments sodium pectate was substituted for salicin in the medium, but growth was unsatisfactory.

Erwinia spp. and *Aerobacter* spp. produce roughly circular, entire, finely granular, yellow to yellowish-orange colonies about 1 mm. in diameter after four days at 26° C. Colonies should be removed to meat infusion agar slopes as soon as possible because they quickly loose viability on the medium. To differentiate between *Erwinia* spp. and *Aerobacter* spp., slices of potato tuber should be inoculated in the usual way.

Although the medium is highly selective, at times pectinase-producing *Pseudomonas* spp. have occurred on the plates. However, they form circular, entire, colourless or very pale yellow colonies, and do not grow in liquid salicin basal-salt media. On one occasion, an organism of the *Bacillus mascerans-polymyxa* group was obtained from the plates.

The medium has been used principally in black leg investigations; but isolations of soft rot coliforms from tomato, celery, etc., have been made successfully.

Studies by one of us (D. C. G.) have recently shown that while *E. atroseptica* always produces alkali in the ethyl alcohol peptone medium of Noble and Marshall[1], this reaction is not specific to the black leg organisms. Certain isolates, identified by other biological and biochemical tests as *E. carotovora* and *E. aroideae*, give the alkaline reaction also. Micro-tests, using washed suspensions in weak phthalate buffer plus 5 per cent ethyl alcohol, were carried out. These showed that acid production in the ethyl alcohol peptone was perfectly correlated with acid production in ethyl alcohol alone. A full report will be published elsewhere.

Seed Dressings for the Control of Frit Fly in Oats

Gough and Woods[1] have shown that the use of a seed dressing of an appropriate insecticide can give good control of damage caused by wheat bulb fly (*Leptohylemyia coarctata* Fall). Moreover, Bradbury and Whitaker[2] have shown that such insecticides as benzene hexachloride, when applied to the roots of a cereal seedling, are taken up systemically by the plant to a marked degree. Cunliffe and Hodges[3] showed that under dry conditions in the spring, the number of eggs of the frit fly (*Oscinella frit* Linn.) laid in the soil around the plant was several times those found on the plant, and this has been confirmed by us using a new technique for recovering eggs. This is being described by one of us (D. P. W.) elsewhere. It seemed, therefore, that an insecticide suitably placed around the roots of the young oat plant might kill some of these eggs or the young emerging larvæ and help to reduce the damage caused by this pest.

Commercial seed dressings of gamma-B.H.C., used for wireworm control, are normally applied at the rate of about 600 μgm. of pure insecticide per gram of cereal seed, but Gough and Woods[1] used dressings of three times this strength (40 per cent gamma-B.H.C. at 3 oz. per bushel). A small pilot trial was laid down by us on April 26 at this centre using oat seed of variety S84 previously treated with a commercial dressing containing an organo-mercurial fungicide. To different lots of this was added further dressings containing gamma-B.H.C., aldrin and dieldrin, each at normal, twice normal and four times normal strength, that is, 600, 1,200 and 2,400 μgm. of pure insecticide per gram of seed. Each plot consisted of 25 ft. of drill sown by hand.

Samples of fifty plants were taken at random from each treatment on June 25, when the very heavy frit fly attack had reached its maximum, and all shoots examined for damage by frit fly. The results (Table 1) indicate the percentage of attack on the primary shoots and on tillers formed later. In a late-sown crop of this type, secondary tillers are produced too late to form a head of grain of any useful size, so the saving of the primary shoot is of major importance in production of a grain crop. These results show that under certain conditions an excellent control of the attacks on primary shoots can be obtained by the higher rates of dressing, especially of dieldrin, and that these shoots can go on to produce a reasonable yield even in late-sown crops.

Table 1

Dressing rate	Insecticide	Primary shoots attacked (per cent)	Tillers attacked (per cent)	Heads per 25 ft. of drill	Yield (cwt. per acre)
	Untreated	94	48	0	0
Normal	Aldrin	52	69	245	6·5
	Dieldrin	32	76	264	9·0
	B.H.C.	60	64	76	2·6
Twice normal	Aldrin	50	73	207	8·4
	Dieldrin	16	68	376	17·8
	B.H.C.	74	74	173	4·8
Four times normal	Aldrin	24	59	350	18·0
	Dieldrin	20	60	346	18·1
	B.H.C.	28	64	246	9·7

Germination at all rates of dressing had been reasonably good, but as the untreated plants rapidly disappeared owing to frit fly attack, a comparison of germination was difficult. It is, however, known that gamma-B.H.C. and aldrin can be phytotoxic in the presence of mercury.

On July 6 a further trial of the same type was sown, but this time using gamma-B.H.C. and dieldrin dressings at four times and eight times normal. Again the untreated control plots were practically destroyed by frit fly attacks, but the dieldrin plots gave substantially the same results as the four-times normal dressing previously used. Severe phytotoxic symptoms were apparent with the eight-times normal gamma-B.H.C. and to a lesser extent with the four-times normal.

In the present trials, seed was sown by hand at a depth of about 1 in. Since under field conditions the seed and dressing might be placed at a much greater depth than this, the insecticides may be less effective against larvæ hatched from the eggs which are laid near soil-level. This aspect is being looked into.

We are indebted to Mr. J. D. Thomas for the original suggestion which gave rise to this work and for reading this communication in draft.

Performance of Telephone Operators relative to Traffic Level

One of the important problems involved in the efficient running of a telephone exchange is to decide on the number of operators required to deal with the expected volume of traffic. Calls arrive at an exchange at approximately random time intervals, so that the longer subscribers wait for their calls to be answered, the less respite will there be for the operators. To provide a service where subscribers rarely wait would require so many operators or trunks that they would be idle for a very large proportion of their time. In practice, a balance is struck between subscriber waiting and operator/equipment waiting.

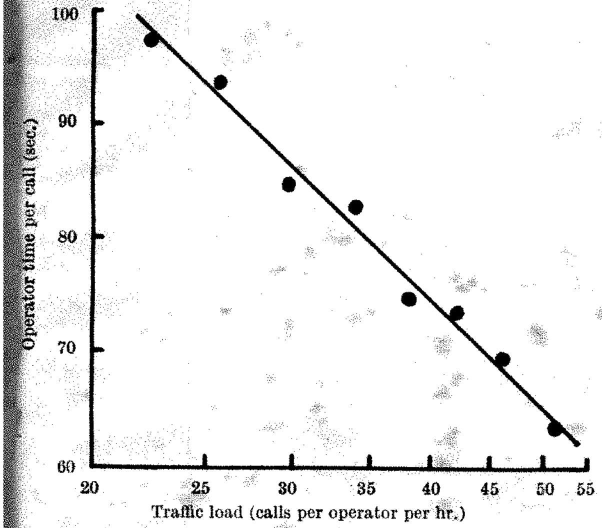

Fig. 1. Relationship between operator performance and traffic level

The mathematics involved in solving this problem for automatic exchanges were first developed by Erlang (Brockmeyer, Halstrom and Jensen)[1]. Subsequent extensions[2] provide a basis for calculating subscriber delay, given the traffic-level, the number of operators available to deal with it, and the operator handling time per call. Theoretically, therefore, one can predict how subscriber delay would be affected if the number of operators at an exchange were to be varied, if one can assume that operator time per call is independent of traffic-level. With the co-operation of the General Post Office this assumption has been tested at a cordless auto-manual exchange by experimentally varying the traffic load per operator during a four-week period. Operator waiting time was measured by Tippett's[3] snap-reading method, and from it, operator time per call was calculated. The result is shown in Fig. 1.

It will be seen that over the range considered, for all practical purposes operator time per call varies inversely as the logarithm of the traffic load on the operator. An assumption of independence is clearly invalid.

Missing Values in Factorial Experiments

Methods of estimating missing values have been discussed by Goulden[1]. Some applications to factorial experiments were presented by Cochran and Cox[2], but they do not give a general formula. If there is one replication of an $a \times b \times c \times \ldots f$ factorial experiment, with n factors $A, B, C, \ldots F$ at $a, b, c, \ldots f$ different levels respectively, then it may be shown by minimizing the highest-order interaction sum of squares that a suitable estimate, y, of a missing value is given by:

$$\begin{aligned}(-1)^{n-1}(a-1)(b-1)(c-1)\ldots(f-1)y = {} & (G)-a(A)-b(B)-c(C)\ldots \\ & +ab(AB)+ac(AC)+\ldots -abc(ABC)-\ldots \\ & \ldots+(-1)^{n-1}\,bc\ldots f(BC\ldots F)\end{aligned}$$

where (G) is the sum of the available observations, that is, the incomplete grand total, (A) is the sum of the $bc \ldots f-1$ observations for the level of A which contains the missing value, or the incomplete A total, (AB) is the incomplete $A \times B$ total, ... and $(BC \ldots F)$ is the sum of $a-1$ observations. There will be 2^n-1 terms on the right-hand side. For two factors this reduces to the well-known randomized-block formula:

$$(a-1)(b-1)y = a(A) + b(B) - (G)$$

The purpose of this communication is to point out that the above estimate has a property which, except for the 2 × 2 table (see ref. 1, p. 310), has not been recorded. The estimate is identical with that obtained by equating to zero a particular component of the highest-order interaction. This is the component, with one degree of freedom, which measures the interaction of the comparisons of the level of each factor in which there is a missing value, with all other levels of the factor. The relation may be verified in any particular case by expanding the above estimation equation in terms of individual observations. This alternative estimate, which will in general be more laborious to calculate, may be obtained by expanding the function:

$$\{(a-1)A_m-\sum_{i\neq m}A_i\}\{(b-1)B_n-\sum_{j\neq n}B_j\}\ldots\{(f-1)F_t-\sum_{k\neq t}F_k\}=0$$

where the product $A_xB_yC_z \ldots F_w$ represents the observation at levels $x, y, z, \ldots w$ of the factors; i, j, etc., run from 1 to a, b, etc., respectively; and where observation $A_mB_nC_o \ldots E_t$ is the one missing.

A more detailed account of these results is being prepared for submission to the *New Zealand Journal of Science and Technology*.

A Mesolithic Burial Tumulus from Ceylon

Stone age burials that have yielded more or less complete skeletons lying in the postures in which they were buried are extremely rare and this is particularly so of Ceylon and India.

Pitted pebble hammers were recorded from Ceylon in 1942 [1], and recently what appears to be a kitchen midden cum burial tumulus yielding more or less complete skeletons of the makers of these artefacts has been discovered at Bellanbandi Palessa at lat. 6° 31′ N., long. 80° 48½′ E., about two miles west of the Valave River. A ridge of reddish earth about 4 ft. high extends across a flat exposure of limestone and contains these bones of humans and of the animals eaten by them, together with stone and bone artefacts, all of the same age and occurring regularly from the surface down to the limestone. This has been eroded to a depth of 4 ft. by a former stream, now represented by a series of temporary pools. The area was divided into 6 ft. × 6 ft. squares and ten of these yielded six more or less complete skeletons. The fragments of about another ten individuals lay either upon or underneath them, together with the remains of the animals utilized as food, numerous stone implements, unworked pebbles, ten pitted pebble hammers and one pitted anvil-cum-grindstone, all akin to those in Fig. 1 of the original article of 1942[1], and with them lay an abundance of microliths with crescents. Most of the pebbles bore scars of impact at either end or along the perimeter. The hammers and anvil-cum-grindstones being of granulite gneiss, amphibolite and basic igneous rock disclosed heavy patination and incipient disintegration; but the quartz and chert artefacts were more or less unaffected by age. Some of the bone artefacts resembled (*i*), (*n*) and (*o*) in Fig. 2 of the previous article[1], and there were also large obliquely pointed digging sticks, spoon-like scoops of bone and deer antler and cells of elephant bone and of antler.

Fig. 1 shows one of these skeletons from square *B* 2. With it are three pebbles and also a bag of thirteen smaller ones, probably sling stones, that had evidently been placed in a bag within reach of the corpse.

The diet of this race consisted of the water snail *Paludomus*, the land snail *Cyclophorus*, the arboreal snail *Acavus*, the reptiles *Testudo* and *Varanus*, mammals such as squirrels, porcupine, hare, monkeys, pole-cat, bear, civet cat, fishing cat, pig, chevrotain spotted deer, sambhur, buffalo and possibly the now extinct gaur.

Materials employed as pigment were lumps of hæmatite and molybdenum worn smooth through friction. The entire skeletons were flexed, the majority facing east or south-east, a few faced north-west, while other skeletons or fragments of such lay above or beneath them. They rested either upon the bedrock or on a rock slab, and were often covered over with another slab. The surrounding limestone had been affected by the decomposing corpse and distintegrated into yellow fragments.

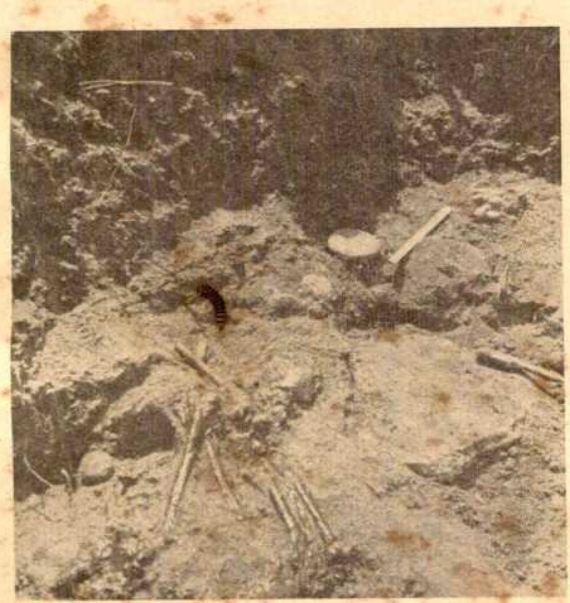

Fig. 1. Flexed skeleton from square *B* 2 lying upon its left side. Pelvis at lower left of figure, a bag of sling-stones near upper or right end of foot ruler

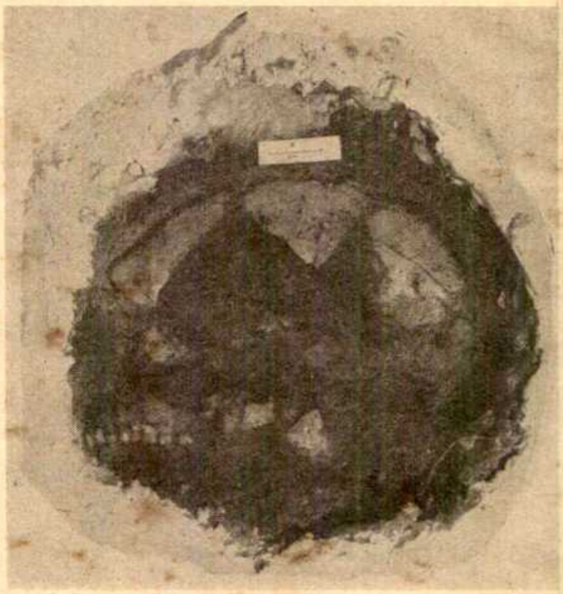

Fig. 2. Left surface of a skull plaster jacketed and lifted from square *B* 2. Its glabellar-occipital length, 223 mm.

The skulls (Fig. 2) were dolichocephalic and prognathous with males possessing heavy diffuse brow ridges and markedly receding foreheads. The bite was of the edge-to-edge type. The skull bones were 8–9 mm. thick. The horizontal mandibular body was noticeably deep.

The teeth were badly worn at an early age, doubtless due to sand in the diet, and the third molars which were usually as large as or larger than the second ones were well worn. Traces of the *Y*-shaped mark generally termed the Dryopithecus pattern were also present in some of the molars.

The abundance of broken bones and human mandibles without calvaria that occurred both loose in the earth and as bone breccia suggests that this site was the kitchen midden of a cannibal tribe that had also ceremoniously slain and interred individuals within it. Fire was known; but its traces were scarce.

The absence of potsherds, the abundance of microliths together with crescents, the unpolished nature of the artefacts, the pebbles with pits produced by conical drilling, the advanced mineralization of the bones, the marked change to aridity of an area that had once been traversed by a large stream from which the aquatic snail *Paludomus* and the arboreal *Acavus* had disappeared, and also the disintegration of some varieties of rock, all indicate sufficient age to support the view that this culture is Mesolithic.

A detailed communication will appear in the Ceylon National Museums Bulletin, *Spolia Zeylanica*.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Tuesday, January 1

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 3 p.m.—Mr. J. F. Coales: "The Evolution of Automation". Christmas Lecture for Older Schoolchildren. To be repeated on Wednesday, January 2, at 3 p.m.)

Tuesday, January 1—Friday, January 4

Geographical Association (at the London School of Economics, Houghton Street, London, W.C.2).—Annual Conference.

Wednesday, January 2

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. W. A. D. Baker: "Approval Tests for Coke Burning Domestic Appliances".*

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Symposium on "Staff Training".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "New Techniques in Photo-Elasticity".

Thursday, January 3

Physical Society (joint meeting with the Institute of Refrigeration, at the Junior Institution of Engineers, 14 Rochester Row, London, S.W.1), at 5.30 p.m.—Mr. M. J. Hickman: "The Thermal Properties of Heat Insulation at Low Temperatures".

Institute of Metals, London Local Section (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. K. Hardy: "The Metallurgical Challenge of Nuclear Power".

Friday, January 4

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. J. M. Alexander and Prof. Hugh Ford: "An Experimental Investigation of the Process of Expanding Boiler Tubes".

Saturday, January 5

British Interplanetary Society (in the Tudor Room, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Dr. Michael W. Ovenden: "Astronomy and Earth Satellites".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Neutron Spectrometer Assistant (at least 27 years of age, and with G.C.E. in four subjects at "O" level, including the English language and a mathematical or scientific subject, or equivalent qualifications) in the Nuclear Physics Division, to assist in the carrying out of slow neutron cross-section measurements on radioactive samples—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 678/34 (January 1).

Chemist (with a good first- or second-class honours degree) at the Central Laboratory, Chiswick—The Recruitment and Training Officer (F/EV.613), London Transport, 55 Broadway, Westminster, London, S.W.1 (January 5).

Superintendent of the Chemistry Laboratories—The Registrar, The University, Sheffield (January 7).

Experimental Officer (preferably with a knowledge of chemistry, routine tests used in clinical pathology, and ability to handle farm animals) in the Radio-Biological Laboratory—The Secretary, Agricultural Research Council's Field Station, Compton, Newbury, Berks (January 14).

Lecturer in Anatomy at the University College of the West Indies—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (January 15).

Experimental Officer (with G.C.E. (advanced) in physics and one other scientific subject, or H.N.C. in applied physics or engineering with a good reading knowledge of Russian and one other foreign language) at the National Physical Laboratory, Teddington, Middlesex, for translating and abstracting from scientific journals—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.423/6A (January 19).

Professor and Head (with high academic qualifications in mechanical engineering, and wide experience in research and teaching in internal combustion and automobile engineering, and in industrial testing and development work) of the Department of Internal Combustion Engineering—The Registrar, Indian Institute of Science, Bangalore 3, India (January 20).

Senior Laboratory Technician (over 35 years of age, and preferably with previous experience in histology and/or microbiology) for basic research in microbiology involving biophysical techniques—The Secretary, Grassland Research Institute, Hurley, near Maidenhead (January 25).

Research Fellow (astronomer, with experience in Milky Way research by observational methods) in the Department of Astronomy, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 28).

Research Scholars (with a Master's degree or equivalent research experience) in the Departments of Astronomy, Geophysics, Nuclear Physics, Particle Physics, Radiochemistry and Theoretical Physics, Research School of Physical Sciences, Australian National University, Canberra, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (January 28).

Chair of Physics in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 31).

Senior Lecturer in Veterinary Medicine (specific and contageous diseases and epidemiology) at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

Lecturer or Assistant Lecturer in Crop Husbandry, at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 8).

Assistant Professor (with an honours degree in mathematics and preferably some postgraduate experience in research or teaching) in the Department of Mathematics—Head of the Department of Mathematics, University of New Brunswick, Fredericton, N.B., Canada.

Biochemist, Basic grade (with experience in steroid chemistry)—The Group Pathologist, The Mental Hospital's Group Laboratory, West Park Hospital, Epsom, Surrey.

Biochemist (with a first- or second-class honours degree or equivalent) to assist in research on amino-acids in animal nutrition; and a Bacteriologist (with a first- or second-class honours degree or equivalent) to assist in work on nutritional significance of micro-organisms of the digestive tract—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Chemist (with at least a four years university degree, and preferably specially trained in physico-chemistry); and a Bacteriologist (preferably with a university degree, and well trained in industrial microbiology) at the Sugar Milling Research Institute, Durban—The Director, Sugar Milling Research Institute, University Private Bag, King George V Avenue, Durban, South Africa, and to the South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2.

Demonstrator in the Department of Physics, University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Demonstrator (with a good first-class degree in science or engineering or equivalent qualification) to teach experimental aerodynamics and to participate in the expanding wind tunnel research activities; and an Assistant Wind Tunnel Engineer (with experience of the operation of large-scale plant involving powers of around 1,000 kW., and sound relevant knowledge of mechanical and electrical engineering techniques) for the operation of a 9 in. by 9 in. continuous supersonic tunnel and an 8 ft. by 6 ft. general purpose low-speed tunnel, and ancillary equipment—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

Laboratory Technician (A.I.M.L.T. or equivalent qualifications) to assist with research work in bone histology—The Pathology Department, Institute of Orthopaedics, 234 Great Portland Street, London, W.1.

Laboratory Technician (male or female, with A.I.M.L.T. or equivalent)—North London Blood Transfusion Centre, Deansbrook Road, Edgware.

Physicist in Charge at the Northern Ireland Radiotherapy Centre—The Secretary, Northern Ireland Radiotherapy Centre, Purdysburn, Belfast.

Principal Scientific Officer (with a first- or second-class honours degree in physics or electrical engineering, and at least three years postgraduate research experience in one or more of the following fields: (*a*) spark or arc discharge process; (*b*) generation of high energy high voltage pulses; or (*c*) capacitor development) to conduct a programme of research into certain aspects of weapon design—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. B/1000/34.

Research Assistants (honours graduates in chemistry) in the Department of Applied Science, Wolverhampton and Staffordshire College of Technology—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

Science Graduate (with a good degree in physics or equivalent, and preferably with previous experience in research) in the Physics Department, for research on the measurement and suppression of dust—The Assistant Secretary, British Coal Utilization Research Association, Randalls Road, Leatherhead, Surrey, quoting Ref. C.84.

Scientist (female, with a first- or second-class honours degree and some research experience) at the National Coal Board's Scottish Divisional Laboratory, Edinburgh, for work mostly concerned with studying the physical characteristics of fine coal and clay suspensions in water and high temperature reactions associated with brick making—The Divisional Chief Staff Officer, National Coal Board, 8 Eglinton Crescent, Edinburgh 12.

Sleeping Sickness Control Officer (preferably single, with a good general education and agricultural training, or knowledge of surveying, mapping, entomology or botany) in the Northern Nigeria Government, Medical Department—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.3A/43728/NF.

Spectrographic Chemist, Research Officer (with at least a university degree with first- or second-class honours, and preferably some experience with spectrographic equipment and methods), with the Australian Atomic Energy Commission, Lucas Heights, Sydney, Australia, to organize a range of spectrographic analytical services and to carry out research on spectrographic analysis generally—The Australian Atomic Energy Commission Liaison Office, Australia Ho[illegible] Strand, London, W.C.2.

Technician in the Chemistry Department—Th[illegible] Royal Holloway College, Englefield Green, Surrey.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Physics in Medicine and Biology. Vol. 1, No. 1 (July, 1956). Edited by Prof. J. E. Roberts. Pp. 102+1 plate. 20*s*.; 3 dollars. Annual subscription: 70*s*. per volume (4 parts); 10.50 dollars in U.S.A. and Canada. (London: Taylor and Francis, Ltd., 1956.) [1710

British Electrical and Allied Industries Research Association. Technical Report L/T 321: The Effects of Small Discharges on Some Insulating Materials—1. By N. Parkman. Pp. 14+11 figures. 12*s*. 6*d*. Technical Report L/T 343: Ultra-High Frequency Breakdown in Irradiated Parallel Plate Gaps. By W. A. Prowse and P. E. Lane. Pp. 6+11 figures. 12*s*. 6*d*. Technical Report L/T 350: A Study of Ionization Coefficients and Electrical Breakdown in Hydrogen. By A. Wilkes, W. Hopwood and N. J. Peacock. Pp. 18+5 figures. 12*s*. 6*d*. (Leatherhead: British Electrical and Allied Industries Research Association, 1956.) [1710

Birkbeck College (University of London). Calendar for the year 1956–57. (134th Session.) Pp. 137+xv. (London: Birkbeck College, 1956.) [1710

Central Electricity Authority. Eighth Report and Statement of Accounts for the year ended 31st March, 1956. Pp. viii+244+8 plates. (London: H.M. Stationery Office, 1956.) 10*s*. 6*d*. net. [2510

Institution of Metallurgists. The Fatigue of Metals. (Lectures delivered at the Institution's Refresher Course, 1955.) Pp. 148+16 tables. (London: Institution of Metallurgists, 1956.) 25*s*. [2510

Imperial College of Science and Technology (University of London). Research Report of the Royal College of Science, 1953–56. Pp. iv+63. (London: Imperial College, 1956.) [2510

Tinplate Handbook: Facts about Tinplate for Buyers and Users. By Dr. W. E. Hoare. Third, revised edition. Pp. 44. (Greenford, Mddx.: Tin Research Institute, 1956.) [2510

Scottish Society of the History of Medicine. Report of Proceedings, Session 1955–56. Pp. 34. (Edinburgh: Scottish Society of the History of Medicine, 1956.) [2510

Royal Institute of Chemistry. Lectures, Monographs and Reports, 1956. No. 3: Coal as a Raw Material. By W. Idris Jones. Pp. ii+22. (London: Royal Institute of Chemistry, 1956.) 4*s*. net. [2510

Scientific and Engineering Manpower in Great Britain. Pp. ii+28. (London: H.M. Stationery Office, 1956.) 1*s*. 6*d*. net. [2510

Piezoelectric Ceramics. Pp. 16. (Towcester: Technical Ceramics, Ltd., 1956.) [2510

Association of Universities of the British Commonwealth. United Kingdom Postgraduate Awards (Fellowships, Scholarships, Grants, etc.), 1956–57. List of Awards tenable at Universities in the United Kingdom. Short list of Awards tenable Overseas. Pp. 130. (London: Association of Universities of the British Commonwealth, 1956.) [2610

Ministry of Labour and National Service. Method of Construction and Calculation of the Index of Retail Prices. Pp. 40. (London: H.M. Stationery Office, 1956.) 1*s*. 9*d*. net. [2610

Ministry of Education. List of Special Schools for Handicapped Pupils in England and Wales (including Boarding Homes for Handicapped Pupils, and Establishments for Further Education and Training of Disabled Persons). (List 42, 1956.) Pp. 72. (London: H.M. Stationery Office, 1956.) 3*s*. 6*d*. net. [2610

Flora of Tropical East Africa. Edited by W. B. Turrill and E. Milne-Redhead. Menispermaceae. Pp. 32. (London: Crown Agents for Oversea Governments and Administrations, 1956.) 3*s*. [2610

Higher Education in the United Kingdom: a Handbook for Students from Overseas. Pp. 203. (London: Longmans, Green and Co., Ltd., 1956. Published for the British Council, and the Association of Universities of the British Commonwealth.) 5*s*. net. [711

The Religious Philosophy of Dean Mansel. By Dr. W. R. Matthews. (Friends of Dr. Williams's Library, Tenth Lecture, 1956.) Pp. 24. (London: Oxford University Press, 1956.) 3*s*. 6*d*. net. [711

Proposals for the Development of the Manchester College of Science and Technology. By Dr. B. V. Bowden. Pp. viii+140. (Manchester: Manchester College of Science and Technology, 1956.) 5*s*. [711

Memoirs of the British Astronomical Association. Vol. 37, No. 3: Edmund Halley, 1656–1742: Papers to Commemorate the Tercentenary of his Birth. Pp. 39+2 plates. (Hounslow West, Mddx.: British Astronomical Association, 1956.) 5*s*. [711

Colonial Geology and Mineral Resources. Supplement Series, Bulletin Supplement No. 1: The East African Rift System. By Dr. F. Dixey. Pp. iv+71+7 plates. (London: H.M. Stationery Office, 1956.) 7*s*. 6*d*. net [711

Aluminium Development Association. Directory of Members. Pp. vi+18. List of Publications. Pp. 31. (London: Aluminium Development Association, 1956.) [711

Empire Cotton Growing Corporation. Progress Reports from Experiment Stations, Season 1955–56. Cotton Research Station, Namulonge, Uganda. Pp. 50. 9*d*. Aden Protectorate. Pp. 14. 9*d*. (London: Empire Cotton Growing Corporation, 1956.) [711

Other Countries

New Zealand. Thirtieth Annual Report of the Department of Scientific and Industrial Research. Pp. 73. (Wellington: Government Printer, 1956.) [1710

Memoirs of the Commonwealth Observatory, Canberra. No. 12: Spectral Types of Bright Southern Stars. By Mary Lee Woods. Pp. 18. (Canberra: Government Printer, 1955.) [1710

Union Observatory, Johannesburg. Annual Reports, 1953–1955. Pp. 16. (Johannesburg: Union Observatory, 1956.) [1710

Chicago Natural History Museum. Fieldiana: Geology. Vol. 11, No. 8: A Review of the Habitat of the Earliest Vertebrates. By Robert H. Denison. Pp. ii+359–458. 1.50 dollars. Fieldiana: Zoology. Vol. 36, No. 2: The Distribution of Fishes Found Below a Depth of 2000 Metres. By Marion Grey. Pp. ii+75–338. 4 dollars. [illegible] 38: Days with Birds: Studies of Habits of Some East African [illegible] By V. G. L. Someren. Pp. ii+520. 8 dollars. Vol. 39, [illegible]ew Birds from Nepal. By Austin L. Rand and Robert L. Fleming. Pp. 4. 10 cents. Vol. 39, No. 2: A New Lacertid Lizar from Angola. By Hymen Marx. Pp. 5–10. 15 cents. (Chicago Chicago Natural History Museum, 1956.) [171

Proceedings of the Symposium on the Physics of Fission held a Chalk River, Ontario, May 14–18, 1956. (Report No. ZECL 329 Pp. vi+414. (Chalk River, Ont.: Atomic Energy of Canada Limited 1956.) 5 dollars. [171

East African Meteorological Department. Pamphlet Series, No. 2 The Climate of Nairobi City. Pp. 4. (Nairobi: East African Meteorological Department, 1956.) [171

Beitrage zur Neotrophischen. 1 Band, Heft 1, 1956. Pp. 68. (Jena Gustav Fischer Verlag, 1956.) 10 D.M. [171

Council of Scientific and Industrial Research. Fuel Researc Institute, Manbhum, Bihar. Carbonization Potentialities of Certai M.P. Coals. Pp. iv+62. (Jealgora, Manbhum, Bihar: Fuel Research Institute, 1956.) [171

United States Department of Agriculture. Technical Bulleti No. 1140: Effect of Spacing on some Agronomic and Fiber Characteristics of Irrigated Cotton. By R. H. Peebles, G. T. Den-Hartog an E. H. Prellsey. Pp. ii+62. (Washington, D.C.: Government Printin Office, 1956.) 25 cents. [171

United States Department of Commerce: National Bureau o Standards. Circular 539, Vol. 6: Standard X-ray Diffraction Powde Patterns. By Howard E. Swanson, Nancy T. Gilfrich and Marlene I Cook. Pp. ii+62. (Washington, D.C.: Government Printing Office 1956.) 40 cents. [1710

Clinica Chimica Acta: International Journal of Clinical Chemistry Vol. 1, No. 1 (January, 1956). Pp. 100. Vol. 1, 1956 (6 issues), 90*s*. Vol. 2, 1957 (6 issues), 90*s*. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1956.) [171

United States Department of Agriculture. Technical Bulletin No 1135: The Larvae of the Phalaenidae. By S. E. Crumb. Pp. ii+356+11 plates. (Washington, D.C.: Government Printing Office 1956.) 1.25 dollars. [171

Federation of Nigeria. Annual Report on the Department o Agriculture (Central), for the year 1953–54. Pp. 52. (Lagos: Government Printer, 1956.) 9*d*. net. [251

On the Genesis of the Ovum of Mammals and of Man. By Kar Ernst von Baer. (Translated into English by Charles Donald O'Malley). (Reprinted from *Isis*, Vol. 47.) Pp. 37+1 plate. (Cambridge, Mass.: History of Science Society, Inc., 1956.) 1 dollar. [251

Arctic Institute of North America. Technical Paper No. 1: The Plankton of the Beaufort and Chukchi Sea Areas of the Arctic and Its Relation to the Hydrography. By Martin W. Johnson. Pp. 32 (Montreal: Arctic Institute of North America, 1956.) 50 cents. [251

Indian Forest Bulletin No. 211 (New Series): Cellulose and Paper Cold Caustic Soda Pulps and Cheap Grade Writing and Printing Papers from Blue Gum (*Eucalyptus Globulus* Labill). By R. V. Bha and P.R. Gupta. Pp. ii+11. (Delhi: Manager of Publications, 1956. As. 12; 1*s*. [251

Chicago Natural History Museum. Fieldiana: Zoology. Vol. 35 No. 4: Placentation of the Pigmy Treeshrew, *Tupaia minor*. By Waldemar Meister and D. Dwight Davis. Pp. ii+73–85+plates 10–14. (Publication 803.) (Chicago: Chicago Natural History Museum, 1956.) 60 cents. [711

Proceedings of a Conference on Tissue Fine Structure held at Arde House, Harriman, N.Y., January 16, 17, and 18, 1956, under th auspices of the Morphology and Genetics Study Section, Division o Research Grants, National Institute of Health. Edited by Keith R. Porter. (Supplement, Vol. 2, No. 4, Part 2, July 25, 1956, *Journal of Biophysical and Biochemical Cytology*.) Pp. xv+454+147 plates. (Baltimore, Md.: Rockefeller Institute for Medical Research, 1956.) 5 dollars. [711

United States Department of Agriculture. Index-Catalogue o Medical and Veterinary Zoology. Supplement 6, Authors A–Z. By Mildred A. Doss, Judith M. Humphrey and Dorothy B. Segal. Pp. ii+1375–1788. (Washington, D.C.: Government Printing Office, 1956.) 1.50 dollars. [711

World Health Organization. Technical Report Series. No. 114: Toxic Hazards of Pesticides to Man—Report of a Study Group. Pp. 52. (Geneva: World Health Organization; London: H.M. Stationery Office, 1956.) 2 Swiss francs; 3*s*. 6*d*.; 60 cents. [711

Mitteilungen des Deutschen Wetterdienstes. Nr. 16 (Band 3): Vorträge über Frostschutz anlasslich der "1. Tagung der Arbeitsgemeinschaft Frostschutz" am 22 November 1955 in Bonn, und de "Sonderbesprechung über die technischen Erfahrungen des Deutschen Wetterdienstes im Frostschutz," am 26 April 1956 in Mainz. Pp. 86. (Bad Kissingen: Deutschen Wetterdienstes, 1956.) [711

Bulletin of the Florida State Museum (Biological Sciences). Vol. 1, No. 3: Freshwater Mollusks of Alabama, Georgia, and Florida, from the Escambia to the Suwannee River. By William J. Clench and Ruth D. Turner. Pp. 97–240 (9 plates). (Gainesville, Fla.: Florida State Museum, 1956.) 1.80 dollars. [711

Publikationer fra det Danske Meteorologiske Institut. Communications Magnétiques, etc. No. 22: On the Computation of Lunar Daily Variations in Geomagnetism—Two Simple Methods. By J. Egedal. Pp. 25. (København: Trykt I Hørsholm Bogtrykkeri, 1956.) [711
